THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

VOLUME XXIV.

FROM NOVEMBER 8, 1889, TO MAY 2, 1890.

(RECAP)

LONDON:
Printed and Published for the Proprietors by GEORGE TUCKER, at the Offices of "THE ELECTRICIAN," Salisbury-court, Fleet-street, E.C.

1890.

Digitized by Google

INDEX TO "THE ELECTRICIAN."

VOL. XXIV.

General Alphabetical Index.

Italic **figures denote that the subject matter is in the "Leading Articles" or in the "Editorial Notes."**

Abandonment of Metropolitan Electric Lighting Schemes, 565.
Abandonment of Proposed London Subway Railways, 283.
Abdank-Abakanowicz Arc Lamp, 376.
Académie des Sciences, The, 233, 488, 541.
Accident to the Electric Light in Vienna, 489.
Accidents to Linemen in New York, 198.
Accumulator, Payen, 233.
Accumulators, Gelatinous Electrolyte for, 613.
Accumulators, Robbery of, 610.
Accumulators, The Regulation of, in Electric Lighting: by G. B. Prescott, 42, 69.
Accumulators, The Theory of, 44.
Accumulators, Use of Cellu'oid in, 639.
Accumulators (*see also* Batteries, Storage).
Actino-Electric Effect of the Ultra-Violet Rays, 233.
Actino-Electric Phenomena, 363.
Actino-Electric Researches of Stoletow, 188.
ADDENBROOKE, G. L.
Electrical Engineering in America, 120, 148, 164.
Underground Mains, 260, 285, 313, 342, 367, 391, 413.
Aden, Severe Storms at, 489.
Adjuster, Telegraph Line, Delany, 152.
"Admiral Nakimoff," The Electric Light Installation on the, 56.
Afghanistan, The Telegraph in, 256.
Agir Motor, 56.
Agitation among Telegraph Clerks, 543, 641.
Agricultural Engineers' Association, 354.
Air Pump, Otto von Guericke's, 233.
Air Temperatures at Great Heights, Determination of, 82.
Alarm Advance Car, Electric, 83.
Alioth Dynamo, 5.
Alternating-Current Apparatus, Some Tests on the Efficacy of: by Dr. Louis Duncan and W. F. C. Hasson, 593.
Alsacienne Dynamo, Brush-holder of the, 138.
Alloys for Standard Resistances, 542.
Alternate-Current Patents, Edison, 629.
Alternate Currents, Some Peculiarities of: by Dr. W. E. Sumpner, 60.
Alternating *v.* Continuous Currents in Relation to the Human Body: by H. Newman Lawrence and Arthur Harries, M.D., 551 (*see also* 539, 555, 563, 581, 604, 611, 629).
Alternating System, Progress of the, in America, 250
Aluminium, Method of Production of, The Pittsburg Reduction Company's, 74, 515.
Alzano (Italy), Alternating-Current Motor at, 639.
Amalgamated Storage Battery Plates, 185.
American Bell Telephone Company, The United States Government Suit against the, 41, 250.
American Electrical Apparatus in the Transvaal, 28.
American Magazines, Electrical Articles in the, 41.
American Opinion on the Deptford Central Station, 352.
American Street Railway Association, Meeting of the, 18.
Ammeter, Compass, Moseley, 483.
Ampere Gauge, 187.
Antilles, the, and Cayenne, Proposed Cable between, 134.
Apparatus, Electrical, for Determining Melting Points, 333.
Arc Lamp, Nine Years with the: by M. D. Law, 504.
Arc Lamp Patent, The "Double-Carbon," 250.

Arc Lamps—
Abdank-Abakanowitz, 376.
Carbon Disc, 386.
Kent, 100.
Lacassagne-Thiers, 45.
Schneider, 471.
Solignac, 330.
Stocher-Sedlaczek, 277.
Westinghouse, 273.

Arc Lamps, Lighting Power of, 9.
Arc Light Formula, Gerard's, 336.
Archangel and St. Petersburg, Proposed Electric Railway between, 363.
Archer Electrical Conduit, 613.
Armature Reactions, Theory of, in Dynamos and Motors: by James Swinburne, 373, 397 (*see also* 335).
Armatures, Compound Conductors for, 507.
Armatures, Winding of, 138, 174.
Aron Meter, Report on: by Gisbert Kapp, 351 (*see also* 335, 379).
Artificial Gutta-Percha, 639.
Artistic Electric Light Fittings, 628.
Asphalte, Mineral Indiarubber, 4.
Association of Metropolitan Electric Lighting Companies, Proposed, 283.
Association of Municipal Corporations, The, and Electric Lighting, 465.
Associations, Electric Light, Establishment of, in America, 352.
Atlantic Cable, Proposed New, to Canada, 309.
Atmospheric Electricity and the Use of Sir William Thomson's Portable Electrometer, Notes on: by C. Michie Smith, 66.
Atmospheric Electricity, Curious Effect of, upon an Underground Telegraph Wire, 446.
Atomic Weights and Magnetic Properties, Relations between, 337.
Attachés, Technical, 159.
Audio Telephone Mouthpiece, 534.
Australasian Telegraph Statistics, 310.
Australia, Progress of the Electric Light in: by E. J. Erskine, 592.
Austria, Telephonic Development in, 629.
Automatic Electric Lamps, 183.
AYRTON, Prof. W. E., MATHER, T., and SUMPNER, Dr. W. E.
Galvanometers, 348.
Ayrton and Perry's Twisted Strip Voltmeter: by Prof. J. Perry, 647.
Back Blocks, 405, 458.
Badt's Handbook of Incandescent Wiring, 45.
Bakery, An Electrical, 488.
Balance, Electrostatic, 30.
Barking-road, Electric Traction on the, 31, 457.
Barraclough's Wire Covering Machine, 530.
Bathurst Improved Back Block, 405.

Batteries (Primary)—
Clark Standard Cell, 356: by Prof. H. S. Carhart, 271, 643; by Lord Rayleigh, 285; by H. H. Hoffert, 327.
Coad, 317.
Dry, 185, 365, 490.
Edison, 158.
Gülcher Thermo, 516.
Hussey Bluestone, 83.
Imchenetzki, 589.
Mehner Dry, 365.
Tatlow, 543.
Weymersch, 454.

Batteries (Storage)—
Eickemeyer, 135.
McLaughlin, 388.
Marx, 542.
Novel, A, 531.
Payen, 233.
Pollak, 515, 563.
Simple, A, 590.

Battery Boxes, Recipe for Making, Watertight, 542.
Baudot Telegraph, 232.
Bavaria, The Telegraph in, 233.
Baxter Motor, New, 105, 125.
Bearers, Steel, Use of, for Overhead Wires, 20.
BELL, Dr. LOUIS.
Electric Motors in General Railway Work, 575, 600.
Test of the New Sprague Street Railway Motor, 247.
Ben Nevis Observatory, Lightning at the, 262.
Benest Submarine Cable Grapnel, 638, 649.
Berlin, Electric Traction at, 541.
Berlin and Vienna, Telephone Line between, 337.
Bermudas-Halifax Cable, The, 3, 282, 337, 590.
BERNSTEIN, ALEXANDER.
Distribution of Electric Energy by means of Constant Current, 84, 107, 112.
Bernstein Automatic Cut-Out for Series Incandescent Lamps, 85.
Bernstein Incandescent Lamp Holder, 86.
Bernstein Regulator for Constant-Current Working, 85.
Bernstein System, 105.
BIDWELL, SHELFORD.
Effect of Tension upon Magnetic Changes of Length in Wires of Iron, Nickel, and Cobalt, 649.
Electrification of a Steam Jet, 149, 227 (*see also* 174).
Bills in Parliament, 284, 310, 414, 440, 466, 490, 515, 639, 651.
Binswanger's High Insulation Ceiling Roses, 380.
Birmingham Exhibition, 2, 88, 412.
Birmingham and St. Helen's, Telephonic Communication between, 336.
Bismuth in the Magnetic Field, 362.
Blackpool Tramway, The, 107.
Blamire's Patent Indicating Apparatus, 433.
Bleaching, Electric, 542.
"Blocking Orders," 207, 335.
Bluestone Battery, Hussey, 83.
BLYTH, Prof. JAMES.
Electrical Oscillation Detector, 442.
Board of Electrical Control in New York, Proposed New, 325.
Board of Health in New York, The, and High-Tension Circuits, 325.
Board of Trade, The, and Electric Lighting Orders, 641.
Board of Trade Electric Light Regulations, Draft, 255, 275.
Board of Trade, List of Intended Applications to, for Provisional Orders, 117, 120, 159, 216.
Board of Trade, Provisional Orders and Licences granted by the, during 1889, 215.
Board of Trade Report on Electric Lighting Bills and Orders of 1890, 466.
Borneo-Singapore Cable, Proposed, 160.
Boston (U.S.A.) Electric Light Committee, Wiring Recommendations of the, 273.
Boston (U.S.A.) Electric Lighting Contract, 325.
Boston, Electric Traction at, 353.
Boston, Overhead Wires at, 226.
Boston, The Fire at, 105, 181, 198, 226.
Bradford Scientific Association, 565.
Brain Work and Manual Labour, 514.
Brake, Electric, Trials, 160.
BRAMWELL, SIR FREDERICK.
Electric Welding, 624.
Brazil, The Rubber Monopoly in, 209, 232, 289.
Brazil, The Telegraph in, 489, 613.
Brazilian Government, The, and the Western and Brazilian Telegraph Company, 17, 96, 256.
Bremen Exhibition, 133.
Brighton, The Electric Railway at, 309.
Bristol University College, 564.
Bristol's Portable Electric Lamp, 581.
British Association Screw Thread, 3.
BROOKS, DAVID.
Underground Conductors, 87.
Brooks System, 79.
Brown, Harold P., and High-Pressure Currents, 2.
Brown System of Electrical Distribution, 80.
Brush Company's Dinner, 231.
Brussels Tramways, 232, 515.
Budapest-Vienna Telephone Trunk Line, 209.
Bulbs, Incandescent Lamp: Frosting, 364; Tinting, 231.
Buenos Ayres and Monte Video, Telephone Line between, 135.
Bunsen Cell, Employment of Chromic Acid in the, 21.
Burglar Alarm, 88.
Burglar Alarm, Jacobus Closed Circuit, 364.
Burmah, The Telegraph in, 541.
Buoys, Incandescent Lamps on, 185.
C. and C. Electric Ventilating Motors, 55.
Cable Interruptions, 107, 282, 309, 590.
Cable Laying, 75, 257, 284, 309.
Cable Rates: Henniker Heaton on, 385; Sir James Anderson on, 463.
Cable Repairs, 21, 232, 257, 336, 362.
Cable Street Railways *v.* Electric Street Railways, 325.
Callender Bitumen Company's Underground Mains, 391.
Callender-Webber Underground Mains, 392.
Canada, Electrical Activity in, 210.
Canadian Telegraphs, 56.
Carbon Deposit in a Blake Telephone Transmitter: by F. B. Hawes, 428.
Carbon Tests: by E. F. Peck, 470.
Carbon Disc Arc Lamp, 386.
Carbonic Oxide Indicator, 364.
Carbons, Electric Arc Light: by O. G. Pritchard, 492, 545, 563, 616.
CARBY, JOHN J.
New View of Telephone Induction, 122.
Cardew Earthing Device, 605.
CARHART, H. S.,
Improved Standard Clark Cell with Low Temperature Coefficient, 271, 643.
Car Service, Electric Practical Points in: by O. T. Crosby, 213.
Cayenne and the Antilles, Proposed Cable between, 134.
Ceiling Roses, Binswanger's, 380.
Celluloid, Use of, in Accumulators, 639.

Central Lighting Stations—
Berlin, 388.
Brighton, 308.
Brooklyn, 227.
Brünn, 488.
Copenhagen, 379.
Dockyards, 135, 257.
Hanover, 389.
Italian, 515.
Johannesburg, 133.
Magdeburg, 387.
Paris, 99, 107, 133, 274, 326, 378, 629.
Pont-de-Vaux, 338.
Rathbone-place, 237.
St. James's and Pall Mall Electric Light Company's, 287.
Salzburg, 337.
Sardinia-street, 309.
Sundsvaal, 378.
United Kingdom, List of, in the, 222, 232, 245.

Central London Electric Railway, 55, 80, 124, 183, 282, 338, 364, 388, 412, 439, 465, 611, 627, 651.
Central Telegraph Staff, Meeting of the, 183.
Ceresin, Electrostatic Phenomena presented by, 353.
Ceuta and Tarifa, Proposed Cable between, 412.
Challenge to the Edison System 250.

24197=cop.2

CHALON, M.
Use of Electricity in Mines, 375.
Charlesworth, Hall, and Co.'s Electric Light Engines, 329.
Chevrant Paper Mills, Transmission Plant at the, 210.
Chicago Auditorium, Lighting of the, 378
Chili, The Telegraph and the Telephone in, 489.
Chilian Import Duties, Repeal of, 3.
China, Electricity in, 299.
China and India, Telegraphic Communication between, 489.
Chlorine Water, Rate of Decomposition of, by Light: by Dr. G. Gore, 114.
Chromic Acid, The Use of, in the Bunsen Cell, 21.
Chronological Chart, A., 640.
Church Lighting, 282, 309, 438, 613.
Church Organs, Electric Power for, 151.
Cincinnatti Inclined Plane Electric Railway, 311.
Circuit Breaker, Young, 378.
City and Guilds of London Institute, 160.
City and Guilds Old Students' Association Soirée, *182*.
City and Guilds Technical Education, *36*, 75.
City Notes, 23, 51, 77, 103, 129, 155, 179, 205, 229, 253, 279, 305, 333, 359, 383, 409, 435, 461, 483, 511, 537, 561, 585, 609, 635, 661.
City and Southwark Subway, 183, 458, 488, 506, 515, *638*.
Civil Engineers, Institution of, 82, 208, 282.
Civil and Mechanical Engineers' Society, 82.
Clark Standard Cell: by Prof. H. S. Carhart, 271, 643; by Lord Rayleigh, 285; by H. H. Hoffert, 327.
Clermont-Ferrand Electric Tramway, 233.
Clock, Electric, An Alternate-Current, 387.
Clothworkers' Company Scholarship, Award of the, 209.
Coad Battery, 317.
Coast Communication, Electrical, *208*.
Code, Government Telegraph, for India, 134.
Co-efficient of Self-Induction of a Single Circular Loop, *611*, 631.
College Lighting, 337.
Colonial Telegraph Statistics, 363.
Coloured Flames, Conductivity of, 364.
Column Printing Telegraph Patents, 184.
Commercial Cable Company, Mr. Mackay and the Staff of the, 232.
Commissioners of Sewers, 387.
Compactum Feed Water-Heater, 459.
Compagnie Continentale Edison, 480.

COMPANIES' MEETINGS, REPORTS, DIVIDENDS, &c.

(Abbreviations:—Div., Dividend; Mtg., Meetings of Shareholders; Rev., Revenue; Rpt., Reports of Directors.)

American Bell Telephone Company—Rev., 537; Div., 333.
Anglo-American Telegraph Company—Div., 305, 561; Rpt., 332; Mtg., 355.
Anglo-Portuguese Telephone Company—179; Div., 537; Rpt., 660.
Australasian Electric Light, Power, and Storage Company—333.
Bedford Electric Lighting Company—Mtg., 607.
Berliner Electricitatswerke—28.
Blackpool Electric Tramway Company—Rev., 103; Mtg., 129.
Brazilian Submarine Telegraph Company—609, 639; Rev., 23, 51, 77, 103, 129, 155, 179, 205, 229, 253, 279, 305, 333, 359, 383, 409, 425, 461, 485, 511, 537, 561, 585, 609, 635, 661; Div., 485; Rpt., 659; Mtg., 21.
Brighton and Hove Electric Light Company—Rpt., 584; Mtg., 659.
British Guiana Electric Lighting and Power Company—661.
Brush Electrical Engineering Company—103, 205; Div., 383, 461; Mtg., 102.
Chelsea Electricity Supply Company—Mtg., 382, 407.
China and Japan Telephone Company—Mtg., 658.
City of London and Southwark Subway Company—Rpt., 358; Mtg., 407.
Commercial Cable Company—229; Div., 561.
Consolidated Telephone Construction and Maintenance Company—Div., 661.
Continental India Rubber Works—Div., 333.
Continental India Rubber and Gutta Percha Company—Div., 609.
Continental Metropolitan Tramways Company—Mtg., 607.
Crompton and Co.—537; Div., 51.
Cuba Submarine Telegraph Company—Rev., 23, 129, 253, 359, 461, 561; Div., 305; Mtg., 357.
Direct Spanish Telegraph Company—Rev., 23, 129, 253, 359, 461, 585; Div., 409; Rpt., 485; Mtg., 534.
Direct United States Cable Company—439; Div., 253, 561; Rpt., 279; Mtg., 303.
Eastern Telegraph Company—305, 613; Rev., 23, 129, 253, 359, 461, 561; Div., 179, 537, 609; Mtg., 277, 302.
Eastern Extension, Australasia, and China Telegraph Company—179, 253, 279, 561, 585; Rev., 23, 129, 359, 461; Div., 537; Rpt., 608; Mtg., 632.
Eastern and South African Telegraph Company—23, 54, 205, 305.
Edison-Swan United Electric Light Company—Div., 333.
Electric Construction Corporation—23, 155.
Electric Welding Syndicate—585.
Electricity Supply Company for Spain—103, 383.
Elmore's Patent Copper Depositing Company—359; Div., 585.
Elmore's Foreign and Colonial Patent Copper Depositing Company—103, 279.
Evered and Co.—485.
Exeter Electric Light Company—Mtg., 485, 561.
Farcham Electric Light Company—Mtg., 585.
Fowler-Waring Cables Company—129; Mtg., 154.
Ganz and Co.—Div., 561.
Globe Telegraph and Trust Company—Div., 253, 537.
Great Northern Telegraph Company—Rev., 23, 129, 253, 359, 461, 485, 585; Div., 179; Rpt., 634; Mtg., 657.
Greenwood and Batley—Div., 51.
Gülcher (New) Electric Light and Power Company—511.
Halifax and Bermudas Cable Company—205, 229.
House-to-House Electric Light Supply Company—Rpt., 660.
Incandescent Gas-Light Company—103.
India-Rubber, Gutta-Percha, and Telegraph Works Company—Rpt., 359; Mtg., 406.
Indo-European Telegraph Company—Rpt., 609; 656.
Liverpool Electric Supply Company—Mtg., 484.
London Electric Supply Corporation—Mtg., 558.
London Platino-Brazilian Telegraph Company—Mtg., 661.
Manitoba Electric and Gas Light Company—179.
Maxim-Weston Electric Company—435; Mtg., 177.
Metropolitan Electric Supply Company—Rpt., 173; Mtg., 202.
Montevidean and Brazilian Telegraph Company—Mtg., 607.
Montevideo Telephone Company—Div., 609.
National Telephone Company—103, 155, 205; Rev., 129.
New Australian Electric Company—Mtg., 510.
Newcastle and District Electric Lighting Company Mtg., 536.
Newcastle Electric Supply Company—Mtg., 511.
Nippon Electric Light Company—27.
Northern Electric Wire and Cable Manufacturing Company—Mtg., 433.
North Metropolitan Tramways Company—Mtg, 359.
Notting Hill Electric Lighting Company—233, 279, 537; Mtg., 484.
Oriental Telephone Company—Div, 561; Rpt., 634; Mtg., 658.
Postal Telegraph and Cable Company—583.
Phonopore Syndicate—Mtg., 205.
Reuter's Telegram Company—585; Rpt., 609; Mtg., 634.
Rochester, Chatham, and District Electric Lighting Company—Rpt., 155.
Schanschieff Electric Battery Syndicate—253, 333.
Schooling and Co.—Div., 537.
Shanghai Electric Company—Div., 383.
South of England Telephone Company—Div., 23.
Spanish National Submarine Telegraph Company—103.
Spiel's Patent Petroleum Engine Company—Mtg., 229.
Submarine Cables Trust—561; Rpt., 661.
Submarine Telegraph Company—Mtg., 606.
Swan United Electric Light Company—Div., 661; Rpt., 23; Mtg., 49.
Taunton Electric Lighting Company—Mtg., 383.
Telegraph Construction and Maintenance Company—435; Rpt., 435; Mtg., 460.
Telephone Company of Austria—179; Div., 561.
Telephone Company of Egypt—Rpt., 511; Mtg., 536.
Telephone Company of Ireland—Rpt., 635; Mtg., 657.
Telephone Company of Rio de Janeiro—82.
United River Plate Telephone Company—485, 537; Div., 229; Mtg., 252.
United Trust Company of New York—359.
Victorian Schanschieff Electric Light and Power Company—537.
West African Telegraph Company—Div., 205.
West Coast of America Telegraph Company—Rev., 23, 129, 253, 359, 461, 561; Div., 229.
West India and Panama Telegraph Company—Rev., 23, 77, 129, 179, 253, 305, 359, 409, 461, 511, 585, 635; Div., 609; Rpt., 22, 659; Mtg., 48.
Western and Brazilian Telegraph Company—17; Rev., 23, 77, 103, 129, 155, 179, 205, 229, 253, 279, 305, 333, 359, 383, 409, 435, 461, 485, 511, 537, 561, 585, 609, 635, 661; Div., 51, 609; Rpt., 22, 659; Mtg., 46.
Western Counties and South Wales Telephone Company—305.
Western Union Telegraph Company—561; Div., 485.
Westminster Electric Supply Corporation—155, 485, 537; Mtg., 459, 537.
Winfield's (Limited)—383.
Woodhouse and Rawson United—23, 51; Div., 305; Mtg., 50.

Companies, New, Registered in 1889, Statistics of, 225, 282 (*see also* New Companies' List on page 7).

Companies Share List, 24, 52, 78, 104, 130, 156, 180, 206, 230, 254, 280, 306, 334, 360, 384, 410, 436, 462, 484, 512, 538, 562, 586, 610, 636, 662.
Companies Wound-up in 1889, 225.
Comparison, A, between the Continental, American, and English Dynamo-Electric Machinery: by Albion T. Snell, 5, 57, 138.
Compass, A Recording, 234.
Compass, The Mariner's, 29, 566.
Competition, Electric Meter, 232, 556.
Competitions, Electrical, 388, 565, 639.
Conductors, Heating of, by Electric Currents: by A. E. Kennelly, 142, 169, 194; by H. Human, 199.
Conductivity, Electrical, of Saline Solutions, 4.
Conductivity of Metals for Heat and Electricity, *336*.
Conductivity of Various Metals, Alteration in the, after a Lengthened Exposure to a High Temperature, 310.
Conduits, Electrical, 29, 613.
Conference, Maritime, at Philadelphia, 3.
Connector, Electric Light Cable, Seely, 517.
Co-Operative Stores, The Electric Light at, 439.
Co-Operative Telephones, 56, *80*, 201.
Constant-Current Transformer with Wattmeter attached, 113.
Continuous Currents from Alternating Currents, Methods of Obtaining, 42, *55*, *106*, 125.
Copper and the Electric Light, 108.
Copper Duty, Agitation for the Repeal of the, in America, 352.
Copper Market, The, 3, 81, 108, 209, 439, 540, 590.
Copper, Tempered, for Electrical Work, 414.
Cost of Electric Traction, *361*, 379, 457, 480, 506.
Costa Rica Cables, Concession for, 4.
Costly Telegram, A, 336

The following Companies have been registered under the Limited Liability Acts:—

American Asbestos Company, 103.
Andrews and Preece, 585.
Argentine Inter-Provincial Railway Company, 279.
Bangwaketsi Concessions Syndicate, 333.
Batava, 77.
Birmingham Electric Supply Company, 179.
Camborne Gas Company, 179.
Compania Madilina del Electricidad, 108.
Durand Electric, Petroleum, and Gas Engine and Manufacturing Company, 537.
Ecuador Central Railway Company, 103.
Egestorff (J. A.) and Co., 661.
Electric Meter Company, 537.
Electrical Engineering Company of Ireland, 511.
Electrical Engineering Corporation, 305, 383.
Electrical Standardising, Testing, and Training Institution 253.
Elmore's Wire Manufacturing Company, 537.
Fareham Electric Light Company, 383.
Foreign and Colonial Electrical Power Storage Company, 155, 511.
Fowler, Lancaster, and Company, 279.
Gas Consumers' Protective Association, 179.
Halifax Mutual Electric Light and Power Company, 23.
Heathley, Janisch, and Co., 179.
Kelvinside Electricity Company, 179.
Key's Electric Company, 485.
Lane-Fox Electrical Company, 383.
Lange and Co, 51.
Liverpool Silver and Copper Company, 129.
Maclellan, P. and W., 409.
Macmahon's Patent Electric Check System, 485.
Mill's Cycle Company, 333.
Morgan's Automatic Electric Signal System Syndicate, 333.
Morris Brothers, 157.
Mutual Telephone Company, 383.
New Asbestos Company, 279.
North African Gas Syndicate, 179, 205.
Norwich Electricity Supply Company, 333.
Oriental Association, 103.
Poole and White, 435.
Popp's Patent, Company to Work, 333.
Priestman Oil Engine American Syndicate, 51.
Purnell High Speed Gas Engine and Manufacturing Company, 305.
Syndicate of Electrical Engineers, 253.
Transvaal Oil Engine Company, 51.
Trent Gas Engine Company, 409.
Trust and Loan Company of China, Japan, and the Straits, 179.
Universal Electric Light and Power Trust Corporation, 383.
Venezuela Telephone and Electrical Appliances Company, 661.
Wrexham and District Electric Supply, 205.
Zurich Incandescent Lamp Company, 564.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 599.—Vol. XXIV. FRIDAY, NOVEMBER 8, 1889. Price Fourpence.

NOTES.

The Institution of Electrical Engineers may congratulate itself on the success of its first experiment in dining, and we have no doubt that last Monday evening's gathering will be repeated every year. On the dinner as a whole—or rather, on the speeches delivered after it—we have commented in our leading columns; but there is one aspect of the scene which could hardly fail to strike any thoughtful observer conversant with the past history of the Institution and with the changes which have come over it in recent years. Evidently the writer of the letter signed "Telegraphy," which appears among our correspondence this week, is keenly alive to those changes, and regards them with little favour. While not endorsing everything that is said in the letter referred to, we cannot but sympathise with a complaint which is in many people's mouths, and to which he is only giving a perhaps over-emphatic but perfectly legitimate expression. The several alterations of title which this Society has undergone have all been in one direction, all conceded by the telegraphic element which was once its mainstay, and all resulting, finally, in the overshadowing and virtual extinction of that element. The title of Electrical Engineer certainly embraces the Telegraph Engineer; nominally it does so, but that it does so in reality is denied by "Telegraphy."

No wonder, therefore, that the numerous body of representative telegraph men who still remain members of the Society under its altered title should feel sore at the treatment they have received, and should now regret their magnanimity in permitting the change to take place. And this more especially if it be true, as alleged, that telegraph men, and telegraphic subjects in which they are interested, receive but scant recognition at the hands of the Council. That, however, is a fault which is capable of correction, and we rather think that Lord Salisbury's speech may help to bring it about. Evidently the noble Marquis had no knowledge of the transformation which the old Society had undergone, the better half of his interesting speech being occupied in proclaiming the political and commercial blessings which the electric telegraph has conferred upon mankind. The other half, although dealing with the distribution of electrical power, was intensely practical, and dealt not with the scientific, but with the social problems which this new rival of steam-power would be likely to solve. Those who thought the presence of the Prime Minister appropriate because of his known predilection for scientific research, would be grievously disappointed; and, perhaps, on reflection they may see in this a reason for reconsidering their attitude towards those practical, if less scientific, members of their Institution whose support has immensely contributed to its prosperity, and whose secession would be a serious blow to its prestige.

A highly sensational account appeared in the daily papers a few days ago of an accident in New York said to be due to a high-tension current from an overhead wire. Our enterprising contemporary, the *Pall Mall Gazette*, promptly interviewed Lord Crawford on the subject, and obtained his expression of opinion that it was a grossly exaggerated account. It goes without saying that our Transatlantic friends are adepts in the art of presenting a very simple story in highly picturesque language. In this case, however, the story as told bears evidence in itself that a liberal use has been made of the scientific imagination in dealing with the facts. It is quite within the limits of probability that an overhead wire belonging to a high-tension circuit should be brought down, and that a horse and his driver may have received severe shocks by becoming entangled up in the wire; but that a wire should "blaze and splutter in the gutter half an hour" *after* it has been severed from the circuit, is not to be accepted on the statement of any reporter.

We have no desire to minimise the danger existing from high-tension overhead circuits, especially when improperly or carelessly put up, or when unlooked-for catastrophes bring them down; but highly-coloured and sensational accounts of accidents so arising only alarm unnecessarily the public mind. The question of overhead wires has got to be faced, and sooner or later they will have to go underground in the United States and elsewhere. The companies need a little pressure continuously applied to bring about this result, but this influence is better brought to bear in the form of a plain and accurate statement of facts, rather than in the form of a highly-exaggerated story in the daily press.

The question of wire gauges is opened up in our columns to-day by Mr. Trotter. Committees may come and Committees may go, but B.W.G. goes on for ever, and not only goes on, but exists in some fourteen different forms, and is only rendered workable by the fact that wire-dealers generally state what they mean by their various sizes. Mr. Trotter is not quite correct, we

Digitized by Google

believe, in saying that the *universal* gauge in American is the Brown and Sharp gauge. The Association of Edison Electric Companies have a gauge of their own. In this gauge the number denoting the size of a wire is the number expressing the nearest whole number of thousands to the expression for the cross sectional area of the wire in circular mils. *Ex gr* No. 10 B.W.G. (usual) wire has a diameter of ·134in., hence its cross section in circular mils. is 17,956, and this wire would be called No. 18 E.S.G. The equivalence of area of wires is, therefore, "figured out" very quickly, and unnecessary strain on intellectual faculties of an order somewhat lower than those of a BIDDER or a BABBAGE is avoided.

MR. TROTTER has done good service, however, by pushing this subject to the front, because it is only by steady persistence that the mental inertia factor resisting desirable change is overcome, and the necessary reform effected. In this, as in so many other things, it is not approach to an ideal system, but uniformity of practice, that is most desirable. The ideal wire-gauge would be one on which calculations as to area and weight are rendered as simple as possible, but it may take some time before we get "wire gauges" and "small screws" into the position of satisfactory unity occupied by the "Whitworth screw."

MR. W. G. GREGORY'S Paper to the Physical Society on a "New Electric Radiation Meter" is an interesting account of an attempt to find a substitute for Hertz's resonator in the detection and localisation of electro-magnetic waves. Further experience with it will, no doubt, result in increasing its sensitiveness. It virtually forms another type of "artificial eye" for appreciating electro-magnetic waves. It may well happen that a physiological study of the retina of the eye, undertaken in the light of recent researches on the electro-magnetic theory of light, may result in greatly increased knowledge of the process of "seeing." We can in this connection call to mind some experiments of Prof. DEWAR'S some time ago, in which he showed that stimulation of the retina of the eye by light produced an electric current capable of being detected by galvanometric means. The electro-magnetic theory of light will have to be supplemented by an electro-magnetic theory of "seeing," at least as far as the actual organ of sight is concerned. Here is work for electro-physiologists.

MR. HAROLD P. BROWN, undaunted in spite of the revelations made by the *New York Sun*, is again on the war path. We have, a few days ago, received from this gentleman a pamphlet headed "Electrical Distribution of Light and Power," which contains a reprint of a lecture he delivered before the Medico-Legal Congress on the fourth of June last, a "partial list of deaths from electric lighting apparatus," and a reprint of an address by a Transatlantic legal luminary on "Legislative Control of Dangerous Electrical Circuits," also delivered before the Congress. If Mr. BROWN were to limit himself to the subject of rendering high-pressure currents safe, every electrical engineer would be in sympathy with him; but he has gone far beyond this mark. His experiments on animals, whilst adding absolutely nothing to our knowledge of the dangers of high-pressure currents, had the effect of alienating the sympathy of his professional brethren, and his excursions under the humanitarian cloak into commercial matters had only the effect of making shrewd business men ask themselves whether Mr. BROWN was not, after al', more concerned with the financial success of some particular system than with the safety of the public. Thus, in the pamphlet before us, we find him again at work trying to prove that the Westinghouse system has a much lower over-all efficiency than the Edison Three-Wire system, and that the latter only requires 25·91b of copper per lamp, whilst the former requires 26·81b. How this statement can be reconciled with the fact that the Westinghouse system has been successful in localities which were hopelessly beyond the reach of the Three-Wire system, we must leave Mr. BROWN to explain.

Burnley.—The Town Council has decided to apply for an electric lighting Provisional Order.

Wigan.—Application is to be made by the Town Council for an electric lighting Provisional Order.

Chelmsford.—At a special meeting of the Town Council last week, the draft licence of Crompton and Co. (Limited) was approved of.

Bucharest.—A 40 years' concession has been granted to a local company for the public and private lighting of a portion of the town.

Walthamstow.—At the last meeting of the Local Board, it was agreed to take steps towards the erection of a central lighting station.

Praham.—It has been decided to introduce the electric light into Praham (Victoria). Messrs. Booth, Ellson, and Co. will probably undertake the work.

Paisley.—At a special meeting of the Council, held on Friday last, it was agreed to apply for a Provisional Order to light the town with electric light.

Wolverhampton.—At a special meeting of the Town Council on Friday last, it was decided that the Corporation should apply for an electric lighting Provisional Order.

A New Use for Electric Motors.—The American Treasury are about to employ electric motors to run the punching machines for cancelling redeemed Treasury notes.

The Woodhouse and Rawson Wiring Tables.—These tables are ready, and can now be obtained from Messrs. Woodhouse and Rawson United, or at the office of *The Electrician*.

Temesvar.—Considerable excitement was caused in Temesvar on Monday night owing to the failure of the electric light. It is reported that some of the underground mains were fused.

Contract Open.—For a complete electric light installation for works in Queen's-road, Victoria Docks, E., for Messrs. W. Goodacre and Sons, Abbey Mills, West Ham, E. Apply to above firm.

Electric Traction in Spain.—Before the close of the year the Bilbao and Portugalete tramway will be worked by electricity. The Madrid Stations and Markets Tramways Company are also going to try the accumulator system.

The Birmingham Exhibition.—The Electrical Exhibiton at Bingley Hall closed on Thursday last week. The Exhibition has been declared a success, and a substantial sum, it is anticipated, will be handed over to local charities.

Machinery Notes.—Ransomes, Sims, and Jefferies (Limited), of Ipswich, are, we hear, extremely full of work in their engine department, having large orders in hand for all classes of engine work, including electric light and mining machinery.

University College, Liverpool.—The Walker Engineering Laboratories at the University College, Liverpool, which have been built and furnished by the liberality of Sir Andrew B. Walker, were opened on Saturday last by Lady Walker.

Digitized by Google

Repeal of Chilian Import Duties.—According to the *Financial News*, the Chilian Government has decided that after January 1st no import duties will be charged on tools, machinery, railway plant, or telegraph or telephone material.

The Telephone in Russia.—The Vienna correspondent of the *Daily News*, writing from the Russo-Polish frontier districts, reports that the different railway stations are being connected by telephone, which spreads to all the military garrisons near the frontier.

An Addition to the Customs Free List in Natal.—A law enacted by the Governor of Natal provides for the admission into the colony, free of Customs duty, of materials required for the construction and maintenance of telegraphs in the Orange Free State and the South African Republic.

Hastings.—The Town Council on Friday last renewed for another year the existing contract with the Electric Light Company for the lighting of the front line from the Queen's Hotel to Warrior-square by fifteen 2,000 nominal candle-power arc lamps, for the sum of £450 per annum.

Deputations at Taunton.—A deputation recently visited Taunton from Barnsley to inspect the electric lighting of the streets. The deputation was unanimous in the opinion that the electric lighting at Taunton was the best that they had seen. Subsequently another deputation arrived from Carlisle.

The French Telegraphs.—The Directeur-Général des Postes et Télégraphes having become aware that the French Telegraph service is inferior in point of rapidity of transmission, and in many other respects, to that of England and Germany, has nominated M. Fribourg to study the question of reorganisation.

Wolverhampton.—The Corporation have refused to grant their consent to the application of the Wolverhampton Electric Light and Power Company, and of the Midland House-to-House Electricity Company, for Provisional Orders. The Corporation have determined to make application for an Order on their own account.

Ramsgate.—The Corporation has decided to take every means of opposing the granting of a Provisional Order in favour of any electric light company. Several members of the Corporation expressed themselves to the effect that it would be suicidal policy to admit the electric light so long as they were proprietors of the gasworks.

Royal Institution.—At the general monthly meeting of the Royal Institution on Monday last, the special thanks of the members were returned to Prof. Dewar, F.R.S., for his valuable present of a portrait of the late Mr. Henry Pollock, and to the Rev. John Macnaught, M.R.I., for his second donation of £50 for improvements in the building.

The Halifax-Bermudas Cable.—On the completion of the cable between Halifax, Nova Scotia, and the Bermuda Islands the British Government proposes to establish a meteorological station at the latter place; and the Government of Canada, in view of the fact that it would be of value to them, are stated to bear half the cost of establishing the station.

British Association Screw Thread.—Mr. Lehmann desires us to say that his address is 38, *not* 28, Hampshire Street, Torriano Avenue, N.W., as it appeared in the report of the proceedings of the London Chamber of Commerce last week. Mr. Lehmann adds that he has been for over five years, and is now, exclusively devoting himself to the practical working out of the Standard Screw Thread.

The Siemens' Five-Wire System.—The municipal authorities of Königsberg are about to carry out an 8,000-light installation on the Siemens' five-wire system, combined with Tudor accumulators. The mains are to be copper rods, resting on porcelain insulators and laid in cement conduits. Three towns will now shortly have the five-wire system in operation, viz., Königsberg, Vienna, and Trient.

Hull.—At the last meeting of the Works Committee it was decided that the Town Council should be recommended to consent to the application of any electric light company prepared to give an absolute undertaking to withdraw their application at any time at the Corporation's request, and that failing such undertaking the Town Clerk should be authorised to apply for an Order on behalf of the Corporation.

Dundee.—The Committee of the Dundee Gas Commissioners has issued a report recommending that the Gas Commission should undertake the introduction of the electric light into Dundee. It has further been decided that the Town Council should apply for power under a special Act to enlarge the representative basis of the Gas Commission, and after that representation had been secured to apply for power to supply electric light.

The Edinburgh Exhibition.—In the Edinburgh Dean of Guild Court last week Mr. R. A. Robertson, on behalf of the executive committee, moved for a warrant to proceed with the erection of the buildings of the Edinburgh International and Electrical Exhibition. The Dean of Guild said he would be prepared to sign the plans as soon as an arrangement was come to with the railway company. The warrant was granted on this understanding.

Military Telegraphists in India.—All the telegraph wires north of Lahore, says *Indian Engineering*, have been placed under the control of Royal Engineers. Soldiers work the line, and officers will be placed in charge, the whole, however, being under the Assistant Superintendent of Telegraphs of that division. Officers will serve until they become proficient in telegraphy, and then they will be succeeded by others. By this means, it is hoped, a large number of officers and men will be well posted in the working of the telegraph.

The Copper Market.—The deliveries of copper during October, according to Messrs. Merton and Co.'s statistics, were as much as 13,890 tons, and the visible stock in England and France and afloat is now reduced to 103,540 tons. At the end of last March the corresponding stock similarly in sight was 124,876 tons, which was the maximum. The rate of decline since that date has therefore been fully 3,000 tons per month. The increase of consumption during October is the more remarkable in connection with the rise of the price of copper, which is now over £44, compared with less than £38 per ton last April.

Lightning at Malta.—The Deputy Governor at Malta has appointed a commission for the purpose of inquiring into and reporting upon the circumstances attendant upon the death by lightning which took place near Rabato, Malta, on the night of the 29th ult., and with reference to the danger or inconvenience which may, in certain cases, result from telegraph or telephone wires fixed against inhabited buildings. The members of the commission are: The Hon. G. C. Schinas, Ph.D., C.E., Superintendent of Public Works; Prof. S. L. Pisani, M.D., Chief Government Medical Officer; Captain Middlemass, R.E.; Prof. H. Magro, M.D.; John McGill, Esq., Eastern Telegraph Company.

Exeter.—Much inconvenience has been caused by the electric light at the theatre suddenly going out on several occasions. For the first two weeks the lighting was very satisfactory, but it is now quite otherwise. On Saturday last (November 2nd) the lights were out for about an hour. The fault is supposed to be in the armature of one of the dynamos. The annual inspection of the Exeter Fire Brigade by the City Council took place on Saturday (November 2nd) when the electric street fire alarms which have only been recently completed, were inspected and tested. The contract for supplying and fixing these alarms has been successfully carried out by Mr. H. J. James, of Exeter.

Edinburgh.—At a special meeting of the Edinburgh and Leith Gas Commissioners, held on Friday last, the Works Committee recommended that they adhere to their former resolution, refusing the Commissioners' consent to any electric lighting company obtaining powers, and that they resolve to oppose any applications for such powers. This was adopted, Bailie Archibald remarking that they must let the ratepayers understand that all the property of Edinburgh and Leith was mortgaged and pledged for the value of the gas to the amount of upwards of one million sterling. There were plenty of places where the electric light companies could try their experiments without coming to Edinburgh.

The Maritime Conference at Philadelphia.—The Committee on Nautical Devices report that they have considered 37 different proposals on night-signalling at sea, but none are equal to the

Digitized by Google

Morse system now in use in many navies, including those of Great Britain, France, and the United States. The Committee also recommend that there should be a fixed *minimum* standard of power for all lights, and, while electric incandescent lamps should be permitted, the use of the arc light at present should be excluded, except for signalling and search lights. One amendment has been carried which provides that the lights carried by ships laying telegraph cables shall be in globular lanterns, instead of a white light, and shall be of a power visible for at least two miles' distance.

Paris Exhibition Honours.—Among the British subjects who receive promotions in or are nominated to the Legion of Honour in connection with the Paris Exhibition are:—Grand Officer of the Legion of Honour: Sir William Thomson, F.R.S. Officers of the Legion of Honour: Sir Douglas Galton, K.C.B., Sir Henry Roscoe, M.P., F.R.S., Mr. James Dredge, Mr. W. H. Preece, F.R.S., Mr. H. J. Trueman Wood, Mr. J. Aylmer. Officers of Public Instruction: Mr. C. V. Boys, F.R.S, Mr. W. H. Massey. Among the French electricians who have been decorated are M. Mascart, who has been made Commander of the Order of the Legion of Honour; MM. Hippolyte Fontaine, Gariel, Menier, Potier, and Weyher, Officers; MM. Berthon, Cance, Lecouteux, Desroziers, Mouchel, Richard, Rouart, Sautter, and Sciama, Chevaliers.

Concession for Costa Rica Cables.—The *Bulletin de l'Electricité* states that the Government of Costa Rica has authorised Señor D. V. Cuenca Creus, concessionnaire of the proposed submarine cables between Venezuela and the United States, to establish direct or indirect telegraphic communication by means of one or several submarine cables with some point on the Atlantic coast of the Republic. The system may touch at one or several points in Central or South America which are as yet unconnected by telegraph on the Atlantic coast of Costa Rica. The concessionnaire binds himself to connect his system with the Atlantic cable which it is proposed to establish between Cuba, Spain and France, *viâ* the Canary Islands. The Costa Rica Government guarantees an annual amount of £1,400, and reserves to itself the right of intervening in the arrangement of tariffs and in the service regulations.

Launceston (Tasmania).—The Launceston City Council have been advertising for tenders for the electric lighting of the city, and have received an offer from the Australian consignee of Ganz and Co. He proposes to utilise water-power to generate the current, which will be sufficient at first to supply 5,600 incandescent 16-candle lamps. The whole of the plant for the installation is offered to the Council for £23,000, which is, of course, exclusive of building, tail-water channel, excavations, and masonry work. The approximate annual cost is put down at £9,554. Another firm have offered to light the city by electricity as a distinct undertaking, or in conjunction with a tramway system, if the Corporation will grant the use of the streets for a sufficient term; but no figures have been submitted. The whole matter awaits a report from the Committee of the Council, to whom it has been referred.

The Relation between Magnetic Disturbances and Earthquakes.—In a note in a recent number of the *Comptes Rendus*, M. Mascart reports that M. Moureaux, who has charge of the magnetic observations at Saint-Maur, has informed him that the magnetic curves for October 25th show indications of disturbances similar to those which have previously been noticed on the occasion of earthquakes, although on that day a copper bar attached to a bifilar suspension did not show the slightest deflection. Since this the papers have announced an earthquake which caused considerable destruction at Gallipoli, and which, from all accounts, seems to have taken place at the moment when the magnetic disturbances were observed at Saint-Maur. If further information confirms the simultaneity of the two events, it would seem that the disturbances of magnetic instruments are not due—in some cases, at any rate—to the mechanical transmission of the shock.

Mica and Glass as Insulators.—Some years ago Warburg showed that when a layer of glass between two mercury electrodes is traversed by an electric current a badly conducting layer of silica is deposited on the side next the anode, and this layer acts just like the dielectric of a condenser, of which the mercury and the glass may be regarded as the two coatings. The result of this phenomenon is that the insulating power of glass at high temperatures increases with the temperature, and at sufficiently high temperature its surface conductivity is reduced to a very small value. Schultze has recently made some similar experiments on mica, which are of considerable practical interest owing to the numerous purposes for which this material is now employed. Schultze's experiments were all made upon sheets of mica split along the plane of cleavage, and he found that their behaviour was exactly similar to that of plates of glass, viz., the first effect of a rise in temperature was to increase the conductivity up to a definite maximum value, after which further increase in the temperature caused a large diminution in the conductivity, which seemed indeed to approach the value zero at very high temperatures. In comparing the insulating powers of mica at various temperatures, both with white mirror glass and thin watch glass, Schultze found that at all temperatures mica was the better insulator.

Mineral Indiarubber Asphalte.—This is the name of a new material, composed of the hitherto valueless refuse of tar, produced during the refining process of tar by sulphuric acid. This secondary produce forms, according to the *Indiarubber Journal*, a black stuff very much like ordinary asphalte, and quite as elastic as indiarubber. If heated in a stove to such an extent that the slimy matter is reduced to, say, 60 per cent. of its former size, a substance is gained as hard as ebony, and dissolvable in naphtha, an excellent non-conductor of electricity, unassailable by acids and alkalies, and therefore very suitable as coverings of telegraph wires and cables. The solution of the mineral indiarubber asphalte, either in naphtha or petroleum, yields a waterproof varnish which remains firm upon metallic objects. The manufacture of the article pays extraordinarily well, as the following figures, taken from the "Société Oleo-Graisse," the inventors and only manufacturers of the material, amply prove:—

	Cost of production per ton. Shillings.	Selling price per ton. Shillings.
Asphalte	16	80
Varnish	16	80
Substitute of ebony	160	1,200
Raw electrical isolating matter	32	400

In the petroleum districts the raw material is almost inexhaustible, and the indiarubber industry has consequently every opportunity of utilising the tar refuse.

The Electrical Conductivity of Saline Solutions.—Numerous experiments on the electrical conductivity of saline solutions have been made by M. P. Chroustchoff. The methods were applied to mixtures of different salts in equivalent proportions. The conclusions arrived at are as follows:—(1) Starting with any system of two salts, the same conductivity is obtained as with the inverse system; (2) the conductivity of the mixture is not the mean conductivity of either system of two salts, nor is it intermediate between the two mean conductivities, but is generally lower than either. This points to a reduction in the number of conducting molecules in the liquid, or, in other words, to the formation of double salts. The typical reaction as represented by the ordinary equation for double decomposition is rarely met with, and in almost all cases the change is complicated by secondary reactions. Other experiments were made with mixtures of two salts which were not likely to interact. The conductivity of each solution was determined separately, and they were then mixed in equivalent proportions. In some cases the observed conductivity of the mixture is the mean conductivity of its constituents; in other cases it is lower. It follows that with the degree of dilution employed there is a reduction in the number of conducting molecules, either by formation of double salts, as with some of the sulphates, or by dissociation by the water, as in the case of zinc acetate. The *Journal* of the Chemical Society points out:—"It is noteworthy that, as a rule, mixtures of salts which crystallise with water have the mean conductivity of their constituents, whilst the conductivity of mixtures of salts which form anhydrous crystals is below the mean."

A COMPARISON BETWEEN THE CONTINENTAL, AMERICAN, AND ENGLISH DYNAMO-ELECTRIC MACHINERY.

BY ALBION T. SNELL.

(*Continued from page 647.*)

Amongst the Continental machines there are a few designs which differ from those types usually regarded as normal. I say normal because, with the exception of the Dezrozier and the *outside armature* Alsacienne dynamos, most of the machines previously referred to belong to types sufficiently common in England to be accepted in ordinary practice. There seems to be in France, as well as in America, a desire to depart from existing types; although such departures oftentimes hint at a want of due appreciation of the advantages of simplicity of design, novelty is good, and if the fundamental principles demonstrated by a costly experience are not neglected to gain the desired end, there can be no objection to the departure. I cannot help thinking, though, that some of the machines shown at the Exhibition have gained novelty at the expense of some of the most important features of design. I will leave the reader to judge whether such be the case, only referring to some of these machines.

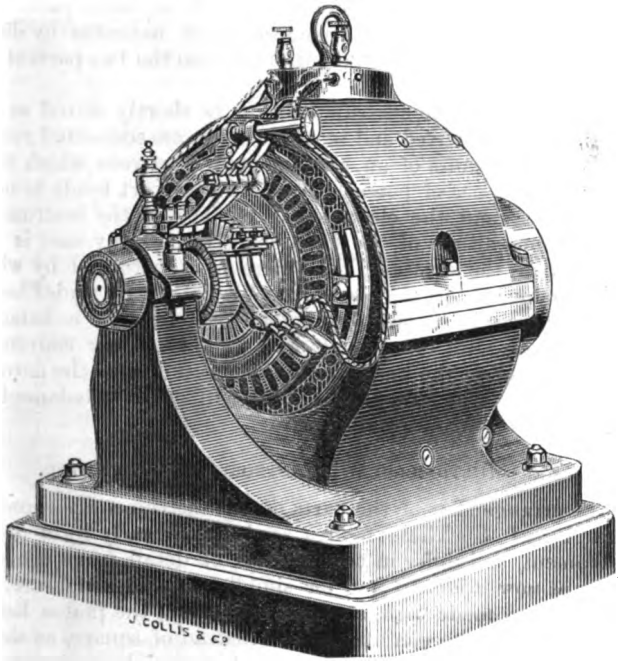

FIG. 6.—The Alioth Dynamo

The Société Gramme have several dynamos designed by M. Deprez. These differ from normal practice in having two armatures to one system of field-magnets, the *second* armature running in the space usually occupied by the yoke. Each armature is independent of the other, as far as the electric and magnetic conditions. Indeed, if mechanical considerations did not make it convenient to mount the two armatures on the same shaft, the dynamo might be considered as two separate machines, and one armature might be run without reference to the other. Since one field is made to excite two armatures, it appears at first sight as if the output per pound of material were largely increased over the normal type. But the double air-gap involved must increase the magnetic resistance of the system very considerably, and necessitates a far greater excitation for a given magnetic density in the armatures. The weight efficiency would thus be probably little, if any, higher. The cost of production must be increased, for the most expensive parts—the armature, commutator, and brushes—are in duplicate. As a set-off to these, there is the advantage that a break-down of one armature will leave the other unimpaired, and space would undoubtedly be economised. This design is also adapted to the multipolar type.

The armour-clad four-pole dynamo of the Alioth Company (Fig. 6) is well worthy of note where a large stray magnetic field is likely to do harm. Mechanically, the design is excellent, for the armature and field windings are entirely surrounded by the circular yoke and the handsome end-covers. The ventilation would appear to be the chief difficulty. This depends almost entirely upon the circulation of air through these covers. To increase this effect, the windings do not entirely cover the periphery of the armature, and spaces are left between the plates at suitable intervals to allow a free circulation of air from the shaft outwards. This manner of ventilating armatures has been patented more than once, and tried with indifferent success by most of the better-known firms. I think, however, that most of them have abandoned the scheme after a few years' trial, preferring to depend on surface rather than internal cooling. An armature is, in the very nature of things, weak, being built up of so many parts. The insulating materials, too, are very uncertain, and generally shrink sooner or later. From the engineering point of view, I much prefer an armature solidly built, with the plates as closely pressed on the insulation as possible, and the whole of the periphery covered with sound insulation and tightly packed wire. The iron plates used in these armatures are one-sixteenth of an inch thick. Judging from my experience, I should anticipate a very heavy loss from Foucault currents, and do not feel surprised that internal ventilation is resorted to on this score alone. The winding is of the drum type and is splendidly finished, each coil being shaped independently in a wood mould.

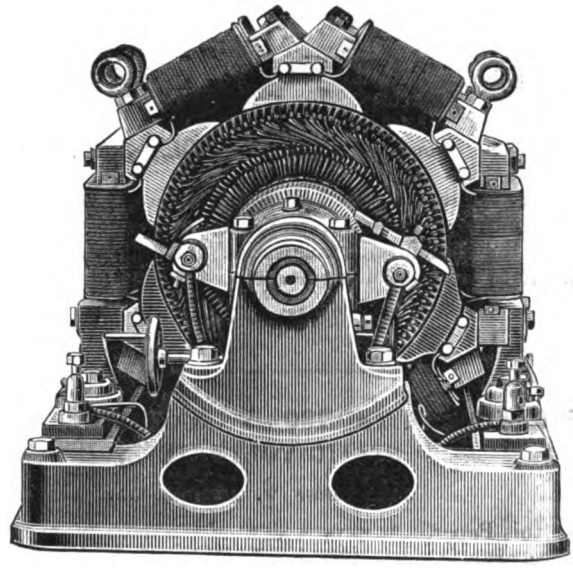

FIG. 7.—The Thury Six-Pole Dynamo.

I shall refer to this when discussing armature winding. Basing my opinion on these criticisms, I should think the weight efficiency was low.

The Thury machine (Fig. 7) is made by Messrs. Sautter et Cie. They exhibit some well finished slow-speed six-pole dynamos, with cylinder armatures and wrought-iron fields of hexagon shape. One of these dynamos, weighing 9,900lb., gives an output of 88,000 watts at 300 revolutions per minute. The surface velocity of the armature is about 2,350ft. per minute. The output is thus very high, 67lb. giving one electrical horse-power. This high weight efficiency is gained by the lavish use of tooled wrought iron in both yokes and cores. Indeed, the field is almost an ideal one from the magnetic point of view. Whether it pays to build such a costly arrangement to gain this efficiency is matter for argument. In England and America the cost of labour would prohibit the design. The illustration will make this clear. The engineering is of the highest order. The joints of the yoke-pieces and the cores are splendidly finished.

Messrs. Sautter, Lemonnier, et Cie. show several cylinder dynamos of the double-field type, with cast-iron pole-pieces and wrought-iron cores (Fig. 8). In these machines apparently cost of production has been kept steadily in view, the result being

Digitized by Google

a somewhat rough-looking, though undoubtedly serviceable, dynamo. The only point I wish to specially note is the radial recessing of the edges of the pole-pieces. This lessens the area of the face of the pole-piece. I assume the makers have found some difficulty with the connections between the armature coils and the commutator. These are a source of considerable trouble with some machines. Connections are continually breaking without any apparent reason. There are two main conditions which appear to cause these breakages. The first is a spring in the shaft, throwing a purely mechanical strain on the connections. The second is the fringe of magnetism around the edges of the pole-pieces, which may cause some considerable work on the adjacent connections. The remedy for the first

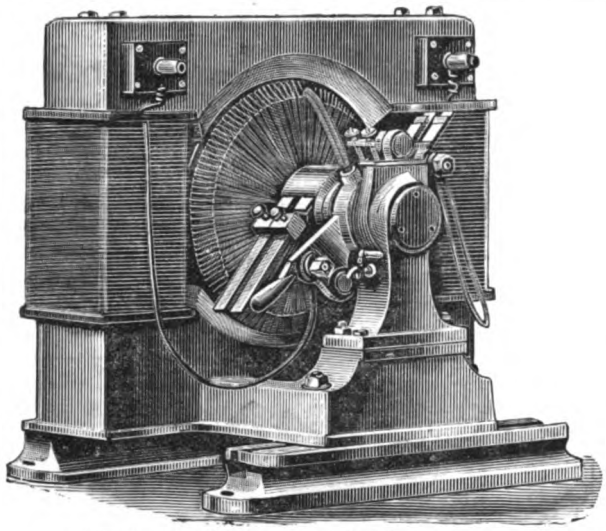

Fig. 8.—The Sautter-Lemonnier Dynamo.

evil is self-evident. The second may be overcome by a suitable arrangement of pole-piece and armature core. I have never known the commutator connections of an Immisch motor or dynamo to break with fair usage.

(To be continued.)

SIR WILLIAM THOMSON'S CHAIN OF ELECTROSTATIC VOLTMETERS.

BY ANDREW W. MEIKLE, M.A.

In this Paper it is proposed to give a description of a chain of electrostatic voltmeters invented by Sir William Thomson, and also to give an account of the methods employed in standardising them. These voltmeters have the great advantage of being equally available as accurate measures of potential on direct and alternating systems; and, being electrostatic, they use no current, and consequently require no temperature correction. They are, therefore, free from the causes of error so prevalent in instruments of the electro-magnetic type, whose accuracy is impaired by variations of temperature, and when used on alternating systems there are errors due to self-induction which vary with the period of alternation. The chain of electrostatic voltmeters measures from 20 to 50,000 volts, and is composed of three distinct types, viz., the Multicellular Electrostatic Voltmeters, the Vertical Scale Electrostatic Voltmeters, and the Electrostatic Balance. The ranges of the separate instruments as usually made are :—

Multicellular Electrostatic Voltmeter	range	20 to	100 volts.
	best of range	25 to	75 volts.
Multicellular Electrostatic Voltmeter	range	40 to	160 volts.
	best of range	50 to	100 volts.
Multicellular Electrostatic Voltmeter	range	60 to	240 volts.
	best of range	70 to	130 volts.
Multicellular Electrostatic Voltmeter	range	80 to	400 volts.
	best of range	100 to	240 volts.
Multicellular Electrostatic Voltmeter	range	200 to	800 volts.
	best of range	300 to	600 volts.
Vertical Scale Electrostatic Voltmeter	range	400 to	8,000 volts.
Vertical Scale Electrostatic Voltmeter	range	800 to	12,000 volts.
Electrostatic Balance.....	range	2,500 to	50,000 volts.

The Vertical Scale Voltmeter has been in use for about three years, but as the demand for it has lately increased since high potential systems have become so numerous, a few words of explanation about its construction and standardising may not be out of place here. It has therefore been included along with the later types in the present description.

Before describing the instruments separately, it may be well to notice some points which concern them all.

The instruments are made on the principle of an air condenser, having one of its parts movable about an axis, so as to increase or diminish the capacity. The condenser is enclosed in a metal case for the double purpose of protecting the movable parts from air-currents and from the disturbing influence of any electrified body other than the fixed portion differing from it in potential. In all the instruments, except the electrostatic balance, the fixed portions consist of two sets of quadrant-shaped cells, in metallic connection with each other, and formed by a number of parallel brass plates. These cells are fixed by an insulating support to the case of the instrument, and a terminal passes from them to an insulating binding screw on the outside of the case.

The movable portions in all the instruments is in metallic connection with the surrounding case. In the Multicellular Voltmeters this connection is made though the suspending wire, and in the Vertical Scale Voltmeter and Electrostatic Balance through the knife-edges, which support the movable part. The movable portion carries the pointer, which indicates by direct readings the difference of potential between the two parts of the condenser.

The action of the instrument may be shortly stated as follows:—When the fixed and movable plates are connected respectively to two points of an electric circuit, between which there exists a difference of potential, the movable part tends to move so as to augment the electrostatic capacity of the instrument, and the magnitude of the force concerned in any case is proportional to the square of the difference of potential by which it is produced. In the use of the Vertical Scale and Electrostatic Balance instruments, this force of attraction is balanced by the horizontal component of a weight of any convenient amount hung on the knife edge in connection with the movable part, while in the case of the Multicellular it is balanced by the torsion of the suspending wire.

The Multicellular Electrostatic Voltmeter.

The arrangement of the parts of this instrument is shown in Figs. 1 and 2. These figures apply to an early form of the instrument, and differ in two matters of detail from the voltmeter as now made. First, for simplicity in manufacture, the cells are now made with straight backs, and the plates looked at in plane are therefore triangular instead of square, as shown in Fig. 2; second, a coach spring has now been interposed between the suspending wire and the spindle carrying the vanes, as explained below. The insulated cells are formed of triangular brass plates fixed into saw-cuts in a brass back piece, so as to be equal distances apart, and accurately parallel to each other. Two sets of these cells, C, are fixed relatively to each other, as shown in Fig. 2, by a vulcanite support to the sole plate, so that their plates are horizontal, and are completely enclosed within the brass cylindrical case of the instrument. On the top of this cylinder is a shallow horizontal circular scale-box containing the scale of the instrument, and having a glass cover, which serves to protect from currents of air the movable indicator I and the scale and interior parts from dust. For the movable part a number of vanes, V, similar in form to those of the quadrant electrometer are used. These vanes are placed parallel to each other on a spindle with distance-pieces between them. The top end of this spindle passes through a small hole in the sole-plate of the instrument, which forms the bottom of the scale-box, and is attached to a small coach-spring, which in turn is secured to one end of a fine platinum wire suspended from a torsion head at the top of a vertical brass tube. The torsion head may be turned by means of a forked key provided for the purpose, and is clamped, to protect it from accidental displacement, by a cap which screws on to the end of the tube. The coach-spring has sufficient resilience to allow the spindle to touch a guard stop, and so

Digitized by Google

aves the suspension from injury in the event of the instrument being roughly set down. Two vertical brass repelling plates, which also act as guard plates to prevent the movable part from turning beyond its prescribed limits, are fixed to the bottom of the sole plate. These two plates carry a guide plate, G, with a circular opening in it, through which the lower end of the spindle passes. A little brass disc, D, or head, is attached to the end of the spindle, sufficiently large to prevent its passing back through the hole in the guide plate. Thus the movable part is effectually secured from swinging about so as to be injured, and by no possibility can it come into contact with the insulated quadrants. When the instrument is level the spindle hangs free by the suspending

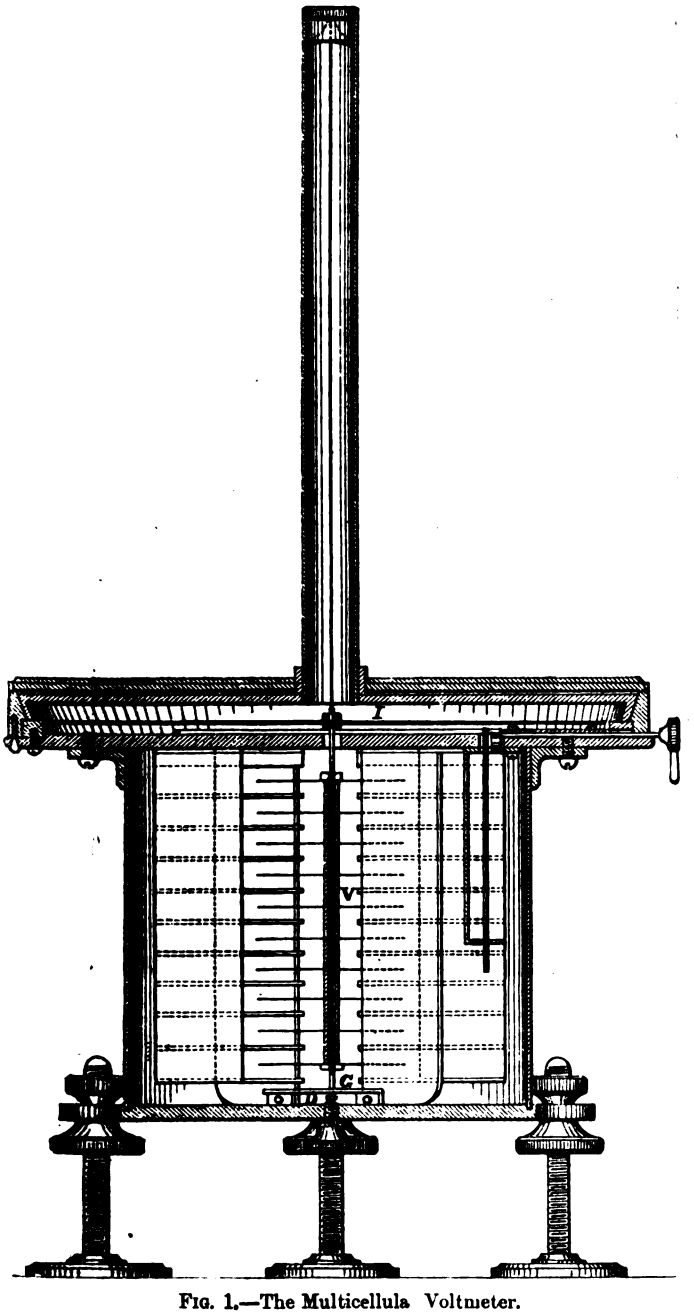

FIG. 1.—The Multicellula Voltmeter.

wire, so that the vanes are horizontal, and each is in a plane exactly midway between those of two contiguous condenser plates. To facilitate the use of the Multicellular as a portable voltmeter, a small thumb-screw is placed in the centre of the base plate below the instrument, which can be screwed in so as to lift the weight of the spindle and vanes from the suspending wire and clamp the disc on the end of the spindle against the guide plate. The instrument is also provided with a "lifter," which serves to raise the weight of the movable part from the suspending wire when it is being moved about from place to place. This lifter is in the form of a ring placed below the needle, and may be raised or lowered by turning the handle attached to an eccentric passing through the side of the instrument on a level with the scale. It also serves as a checker, by bringing it lightly into contact with the pointer, so as to stop its vibrations. An aluminium needle, I, attached to the top of the spindle, indicates, on the horizontal circular scale fixed to the upper side of the sole plate, the difference of

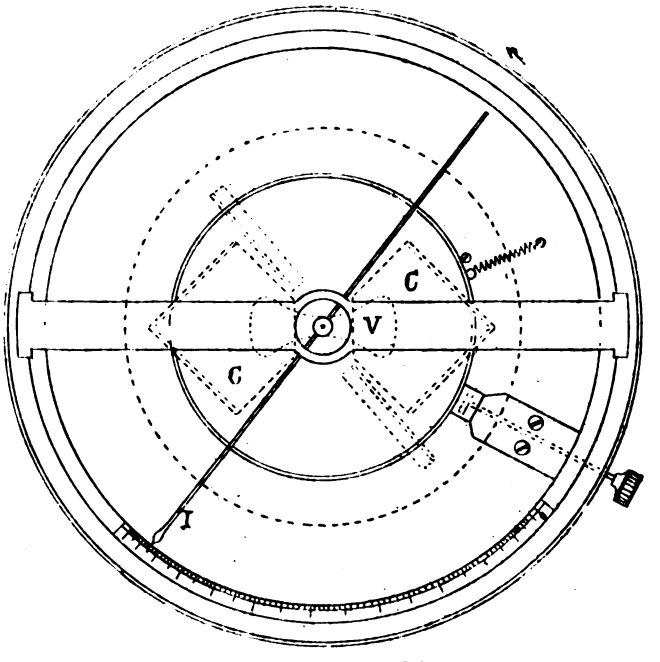

FIG. 2.—The Multicellular Voltmeter.

potential between the movable and fixed portions of the condenser by direct readings in volts. To enable this multicellular to be used as an inspectional instrument capable of being read from a distance, as across an engine room, a mirror, supported

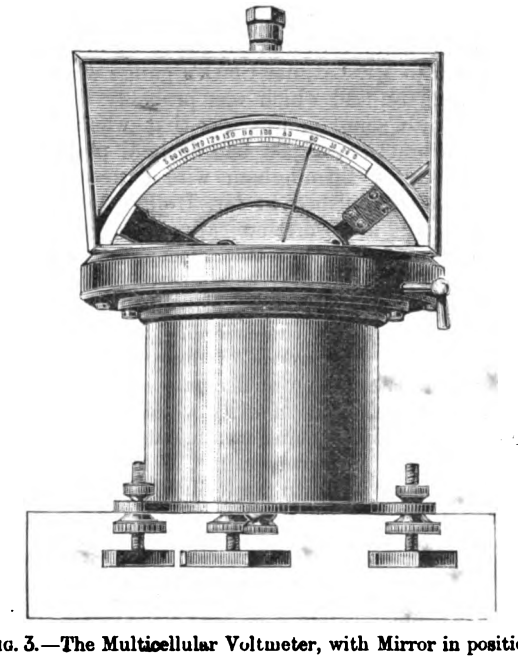

FIG. 3.—The Multicellular Voltmeter, with Mirror in position.

in a frame which passes over the vertical brass tube and rests upon the glass cover of the instrument, is supplied. When this mirror is in position it is at an angle of 45° with the plane of the sole plate, and by reflecting the scale and pointer, gives the instrument all the advantages of a vertical scale. The instrument is shown in Fig. 3 with its mirror in position.

The different sensibilities required for the different types of this instrument are obtained by varying the number of cells and vanes, and also by using suspending wires of different cross section.

WIRE GAUGES.

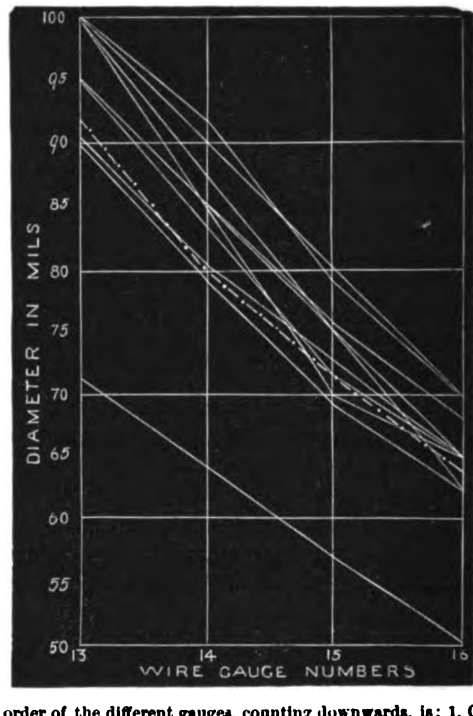
BY ALEX. P. TROTTER.

Just ten years ago there was published by the Society of Telegraph Engineers a report of their Committee on the Birmingham Wire Gauge, together with Papers on the same subject by C. V. Walker and by Latimer Clark. The report describes some fourteen different gauges, and goes into the history of the subject. It suggests that the origin of the numbers by which the sizes are denoted, is based on the number of times which the original rod had passed through the draw-plate. Mr. Latimer Clark points out that, on the one hand, the manufacturer would naturally endeavour to draw down as small as possible at one operation, in order to save labour; on the one hand, he would be limited in this by the strength of his men or the machinery in use before the introduction of steam power, and by the cohesive strength of the material itself. It is not surprising, if this explanation be the correct one, that the sizes of the Birmingham wire gauge, as given by twelve different authorities in an appendix to Mr. Latimer Clarke's Paper,* should differ considerably among themselves, while they all follow a fairly general law. This law the author attempts† at some length to prove to be a logarithmic series; he accounts for variations from it by peculiarities in the physical properties of metals, and adds that had all the wires from which the Birmingham wire-gauge series were originally drawn been perfectly pure and homogeneous, there can be no doubt that the succession of numbers would have had a common factor of reduction, and formed therefore a logarithmic curve. He suggests, then, as the basis of a new standard gauge, a logarithmic series, in which at any part of the scale the weight of the preceding size is 25 per cent. greater, and the succeeding 20 per cent. less, than the size from which one starts. The Committee selected this gauge from the thirteen others, and recommended its adoption as a standard, since, being a geometrical system, it can be extended indefinitely in either direction, and a person knowing the weight or conductivity of any one size can readily calculate the others. They pointed out that it conforms closely to most of the Birmingham gauges, although the extreme numbers, both large and small, exceed the ordinary Birmingham gauge by more than one size. One objection to Mr. Latimer Clark's gauge which was noticed by the Committee, and which was probably the reason why it never came into common use, was that when defined in mils it requires in practice at least one decimal place. Among the numerous so-called Birmingham wire gauges was one whose dimensions were published in Mr. Holtzapffel's book on Turning, and his well-known mechanical accuracy gives considerable weight to the authority of the table;‡ but even this is far from a regular series, as may be seen by plotting it on a curve, or by taking the differences between the successive sizes. The arbitrary irregularities of the different gauges on the one hand, which might make a difference of many thousand pounds to a contractor, and the numerous decimals of the geometric series on the other, was a choice of evils which the recommendation of the committee did nothing to alleviate.

In America the universal gauge, if the expression be permissible, is that of Brown and Sharp. This appears to be ill-suited to that country, for it is a geometric gauge, each size being multiplied by 0·890522 (or deducting 10·9478 per cent.) to form the next size. This involves the use of a considerable number of decimals, the usual table§ being carried to five places. If one may attempt to use their expressive vernacular, while you are figuring out a lot of peaky decimals a practical man will locate a 10,000-light plant right away. A more suitable gauge for our Transatlantic friends would be one whose sizes are denoted by fractional parts of an inch. One could then make two cuts on a hammer handle, wind the wire round and round, and then count the turns.

The Post Office has for many years specified the size of iron telegraph wires by the weight per mile. This system presents the advantage of the use of a unit which is directly proportional to the conductivity and cost; but it is applicable to only one material. In such manufactures as rabbit netting, wire rope, needles, &c., only a few sizes are required, and the maker would probably detect any variation in the diameter by comparing the dimensions or bulk of the finished article with its weight; but during the last five or six years the development of the manufacture of dynamos and electrical instruments has made the exact specification of the diameter of wires an absolute necessity. Five years ago, Gramme armatures were wound with 400ft. of No. 18 per arc lamp, and four or five mils or so one way or the other did not matter in the least. But nowadays the utmost nicety of calculation is often needed to bring a dynamo within the limits of weight prescribed by the Admiralty, or to squeeze a stock size to meet an intermediate output. Again, to calculate a special shunt-winding for a specified output and speed implies the use of an accurately determined size or sizes of wire.

The ambiguity existing among the fourteen versions of the B.W.G. at first sight appears to be serious, but now that every electrical wire dealer gives a table of the sizes expressed in decimals of an inch, the difficulty, as far as the execution of orders is concerned, vanishes. In other trades where the inconvenience of ambiguous gauges has been felt, the example of the electrical trades may be followed, and the diameter may be specified in mils.



At 13¾ the order of the different gauges, counting downwards, is: 1, Cocker [steel] (*The Electrician*, Vol. II., p. 286.); 2, Cocker; 3, Schaw (*The Electrician*, Vol. II., p. 8); 4, Bartholomew; 5, Whitworth, Henley, Culley, Rylands (*The Electrician*, Vol. I., p. 191); 6, Holtzapffel [also Stubbs]; 7, Latimer Clark; 8, Board of Trade S.W.G.; 9, Rylands, 1866, Brown and Sharp.

At 15½ the order is: 1, Cocker; 2, Cocker [steel] (*The Electrician*, Vol. II., p. 286); 3, Bartholomew; 4, Henley, Culley, Rylands (*The Electrician*, Vol. I., p. 191); 5, Schaw (*The Electrician*, Vol. II., p. 8); 6, Latimer Clark; 7, Molesworth; 8, Board of Trade S.W.G.; 9, Whitworth; 10, Rylands, Brown and Sharp.

But certain authorities discovered, either by pure deduction, or by observation of some dispute or litigation, that a contract merely specifying a certain size of B.W.G. was loose, and even a judge and jury could not determine its exact meaning, although the inch, and therefore the thousandth part of an inch, yet remains as an imperial measure by which the contract might have been exactly particularised. They, therefore, by way of mending matters, devised the S.W.G., and in March, 1884, it became a legal measure. At that time the writer, who was then commencing to build dynamos, thought that the general introduction of the new gauge would be a matter of a few years, and to avoid future trouble he adopted it at once. Some time elapsed before he discovered that the wire, which was carefully specified in S.W.G. and in mils, was specially drawn for his firm, whose order would have been executed, at all events in part, from stock the next day, had B.W.G. been specified, but who were generally kept waiting for

weeks. Plotting on a curve (see diagram), the standard gauge, together with the different versions of the B.W.G., the former is found to follow the general sweep of the latter more closely than does Latimer Clark's logarithmic gauge. But the sizes are smaller than the various B.W. gauges. If this had been intended as a restoration of the great original B.W.G., the difference might be due to an attempt to eliminate the effects of wear on the notches by which wires are measured, but there is no reason to suppose that this is the case. A careful inspection of the figures show that the differences run in groups, and do not give a gradual increment, as in geometrical systems. For example, between 23 and 19 the diameters increase by 4 mils, between the next four sizes 8 mils, the next two sets of four—that is up to No. 7—by 12 and by 16 mils respectively; then three sizes differ by 20 mils, and then a group of five with an increment of 24 mils. Decimals of a mil are not required above No. 27. The S.W.G. is convenient, since it closely follows the sweep of the numerous versions of the B.W.G., and it is sensible in its method of increase and in its freedom from decimals; but there its value seems to stop. Were it universally adopted, there would, doubtless, be little or no fault to find with it, but where is the inducement to adopt it? From the legal point of view, surely, a contract which specifies the diameter in decimals or fractions of an inch is sufficiently explicit, and it is questionable whether a wire dealer who issues a printed list containing two columns, one of B.W.G., the other of dimensions expressed in parts of an inch, would not be held to his list in a court of law if his customer had merely specified a certain number "B.W.G." If the dealer issued no such list, then, *caveat emtor*, the comparative lightness of the S.W.G., if enforced by the judge, would be against the purchaser. Surely the gauge was not so arranged to encourage the buyers to use it?

If we put decimals of the imperial inch and the possible results of litigation on one side, there is little to choose between one gauge and another, whether geometrical or arbitrary. The question becomes reduced to one of convenience. Every dyname maker but the humblest must keep a ton or two of wire in stock, and finding that his favourite dealers do not stock S.W.G. sizes, he naturally tries to work in with B.W.G., that his orders may be executed promptly. The dealer on the other hand, finding that few, if any of his customers ask for S.W.G., has no reason to push it, and under the circumstances it is not easy to see why either party should trouble themselves to be the first to make the move.

LIGHTING POWER OF ARC LAMPS.

In Berlin the civic authorities, in specifying their requirements in respect of the electric light, stipulated that the arc lamps to be supplied in "Unter den Linden" should be run with a current of 12 amperes, and give a light of 2,000, or, in some cases, of 5,000 candles. Herr Elston considerably startled all parties interested, and gave rise to an animated discussion, by affirming that the actual lamps did not, in point of fact, give light exceeding 500 candles, and that this materially affected the price of light produced by electricity. The Allgemeine Elektricitäts Gesellschaft of Berlin instituted a series of experiments in the electro-technical laboratory of the High School of Berlin, under Prof. Slàby; and, on the results of these experiments, Dr. Wedding gave a lecture, which itself gave rise to a good deal of discussion. Dr. Wedding asks, after considering the recent development of the demand for intense light, What is the meaning of the expression, "a 2,000-candle arc lamp"; is it with or without a globe; is it at any given angle, or is it an average intensity?

The first difficulty in the research conducted in the High School was that which never fails to present itself, the imperfection of photometrical methods. Measurement of light in one direction is, with an arc lamp, not sufficient; the intensity varies according to the direction: and measurements must run through at least 90deg., from a horizontal direction to one vertically downwards; or, for a closed room, through 180deg., from vertically above to vertically below the lamp. The measurements hitherto made at various angles have been made with the aid of mirrors. Dr. Wedding's experiments were on one of the Unter den Linden lamps, a Siemens' differential. The current supplied, as regulated by the Allgemeine Elektricitäts Gesellschaft, was 14 to 15 amperes at 48 to 52 volts, produced by a Schuckert compound dynamo worked by the gas engine of the laboratory. The rooms were high, and the intensities in various directions were thus measured directly, without mirrors; the photometer used was Elster's modification of Bunsen's. The carbons very rarely burn evenly; then the two sides are not equally illuminated: by using two photometers, one on each side, the average intensity may be found and recorded. The unit adopted was the German candle, trimmed so as to burn with a flame 1·8 inch high; this nearly coincides with the English standard candle. The intermediate light chosen was produced by Albert gas burners; any difference of colour (one side of the photometer disc red, the other side blue) becoming, after some hundreds of observations, insignificant to the experienced eye.

The intensity in a horizontal direction was very small (without globe, average 196 candles); it rapidly increased till about 20deg. (about 1,150 candles), attaining a maximum (about 2,014 candles) at about 42deg., and then began to sink rapidly; at about 60deg. there was no light, but shadow. The average intensity over the illuminated area was, without globes, about 1,228 candles. With globes, the photometric work was much more difficult than without them. With three given globes, the average intensities were:—

——	Horizontal.	Maximum.	Average intensity.
Globe I.	419	970	710
„ II.	519	1,093	777
„ III.	497	713	590

The horizontal light was thus absolutely greater with a globe. On the whole, the loss ranged from 40 to 53 per cent.; and this may be diminished, by the use of a reflector, to a loss of about 32 per cent. Tracing out, in the street lighting, the illumination of various points at a height somewhat less than that of a man's head, a series of curves was obtained which show that, with the average data given by the above measurements, and with the lamps at 26ft. 8in. above ground, the light necessary for reading (=10 candles at 40in.) is obtained for a distance of 53ft. from the lamps. The lamps are 137ft. apart. In the intervals the light sinks to 4½ candles at 40in.

Dr. Wedding thus finds the actual lighting power of the Siemens differential arc lamp, as used in Berlin, with the globe on, to range from 510 candles directly downwards to 1,183 in a downward direction inclined 40deg. to the horizon, and 640 at a downward slope of 5deg. Dr. Wedding had the lamps clean and bright in the laboratory. His broad result is that with the most transparent of the globes supplied him, and with freshly-whitened reflectors, the average lighting power was 834 candles. Herr Elster, in actual street measurements, obtained an ultimate average of 641 candles; his earlier results were below this, being about 500 candles.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

MONDAY, November 11th.

LONDON CHAMBER OF COMMERCE.

4 p.m. Special Meeting of the Electrical Trades' Section.

TUESDAY, November 12th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Inaugural Address of Sir JOHN COODE, K.C.M.G., President, and Presentation of Medals, Premiums, and Prizes awarded at the end of last Session.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture, "The Heart and How it Beats." By W. FURNEAUX.

WEDNESDAY, November 13th.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting.

THURSDAY, November 14th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. "On the Lighting of the Melbourne Centennial International Exhibition." By TH. L. MURRAY, Member.

FRIDAY, November 15th.

PHYSICAL SOCIETY.

5 p.m. "On Electrifications due to the Contact of Gases and Liquids." By J. ENRIGHT. "On the Effect of Repeated Heating and Cooling on the Electrical Resistance and Temperature Co efficient of Annealed Iron." By H. TOMLINSON, F.R.S. "Notes on Geometrical Optics." Part II. By Prof. S. P. THOMPSON, D.Sc.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. "The New Harbour and Breakwater at Boulogne-sur-Mer." By S. C. BAILEY, Stud. Inst.C.E.

Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, 1, *Salisbury-court, Fleet-street, London, E.C.*

THE INSTITUTION OF ELECTRICAL ENGINEERS.

THE INSTITUTION OF ELECTRICAL ENGINEERS has taken one more step in imitation of that older society on the lines of which it is worthily modelled, in inaugurating an annual dinner of its members. The first of these social conventions (the proceedings of which are fully reported in our columns) may be fairly looked upon as a successful innovation. The Anglo-Saxon race is characterised by its faculties for self-government and colonisation, and amongst its minor specific qualities may perhaps be included that of dining together in aid of, and celebration of, various events. Two years ago the members of the electrical fraternity met and dined in commemoration of the Jubilee of the Electric Telegraph. The present reunion may be considered to mark not so much the recollection of that which is past, as the recognition of present facts and future hopes. It was a happy selection which placed SIR WILLIAM THOMSON in the Presidential Chair during the first year of the existence of the Society under its new style and title. The change of name of the Society was something more than the change of a somewhat cumbersome denomination into a more brief and business-like name. It was a mark and indication of the fact that a change had come over the spirit of the dream, and that applied electricity could no longer be spoken of as comprising only telegraphy and telephony, but had grown up into a constructive science concerned with the manipulation of special forms of energy applied in many diverse but equally important ways to the satisfaction of the requirements of practical life. It was, moreover, an indication of the fact that the era had arrived at

Digitized by Google

which the practical applications of electricity had become sufficiently numerous to justify a title covering not one, but all of them, and which should at the same time emphasise the fact that the main objects of the Association were not the accumulation of fresh information, with possible future applications, but the practical applications in constructive work of that already existing to meet the wants and extend the powers of modern man. The SOCIETY OF TELEGRAPH ENGINEERS AND ELECTRICIANS therefore, after eighteen years of useful work, to metamorphosed itself into an INSTITUTION OF ELECTRICAL ENGINEERS, and it did certainly well in selecting as its leader, in the first year of its transformation, the present illustrious President, whose long range of scientific work has extended into the domain of practical and engineering construction with as much force and effect as it has into the region of mathematical and experimental physics.

The establishment of an Institution Dinner may be in one sense an affair of quite minor importance. What more natural than that the members of a definite profession, drawn every day into closer relations with one another, should desire to imitate the example of the other learned and professional societies who in the same way effect a social union of their members? On the other hand, there is an aspect of this event which is of much greater significance than the mere assembling round a table of a number of scientific men and their distinguished guests. It is the outward and visible sign of the fact that the electrical engineer has taken a definite position, and has a recognised existence in a way not consciously felt a little time ago. He is no longer one of a somewhat indiscriminate body, for the most part semi-practical, or engaged in occupations having a very problematical future, but he exists as a member of a particular branch of the great confraternity of engineers, requiring a particular and special training for his career, and having a work of immense importance, to which he devotes his trained constructive skill and invention. In a passage of his eloquent and suggestive speech LORD SALISBURY regrets that historians have marked out the history of the human race into periods defined so much by the rise and fall of dynasties rather than by the appearance and development of those great inventions which are really the determining forces at work in moulding the ideas and habits of the human race. Antiquarians speak generally of a stone age, a bronze age, and an iron age; but the invention of printing by separable type, the combination of a steam cylinder and separate boiler and condenser, and the discovery of the facts of electro-magnetism and electro-kinetics are more definite and more important epoch-making events in the history of the world. The fact that the mechanical and civil engineers have laid their hands on the electric current as a means of extending the facilities of modern life, and the fact that the knowledge of processes and materials has become sufficiently advanced for them to do so, is one of those steps forward in the extension of human powers which has now taken place and brought into existence the profession of the electrical engineer. Not, however, be it remarked, consisting in the acquirement of a little engineering information by a student of electrical book or laboratory lore, but by the assimilation by the mechanical and civil engineer of a competent knowledge of those facts concerning electricity which are capable of being brought within the scope of engineering work. Already the human race has felt the power of this combination of the engineer and the electrician. He has commenced his operations by practically diminishing the size of our planet a million-fold. "He has assembled mankind," as LORD SALISBURY says, "on one vast plane where they can see everything that is done and hear everything that is said, and judge of every policy which is pursued at the very moment when those events take place." There are now no foreign lands. Every place to which a wire, insulated in air or laid under sea, is conducted by the electrical engineer, is, for countless purposes, placed in immediate contact with its imperial centre. And not merely in mere simultaneous knowledge of events is this new power felt: the power of simultaneous action is even more tremendous in its results. The PRIME MINISTER raised the veil for one instant from off the mechanism of Government in touching upon that incessant and instantaneous exchange of opinion and decision between those individuals who hold the reins of power in Europe, and for whom the electric telegraph serves the double purpose not only of ascertaining facts or feelings, but of enabling them to put in simultaneous motion all parts of that immense machinery of offence and defence of which the armaments of Europe are the active parts. The electrical engineer has not only revolutionised the conditions under which the politician and statesman work, but has done the same for commercial life, as those know full well who have lived across the period before and after the existence of submarine cable enterprise. His scope of action seems almost unlimited in altering the conditions under which human beings work. If the invention and perfection of the steam engine has acted as a concentrative power upon human life, necessitating the aggregation of men and women in great cities and in huge factories, the electric engineer posseses the magic wand which can, perhaps, reverse in the future some part of this process, and bring the power to the worker rather than the worker to the power. This question of the distribution of power is one the mere fringe of which has only yet been touched. That which blocks the way at present, and to which the electrical engineer requires to direct his most fertile invention, is the perfection of underground conductor systems. The diffi ulties of this are by no means as yet completely overcome, and to the electrical engineer of the present falls the task of grappling with those real and existent difficulties which seem often non-existent in the minds of those who are more electricians than engineers. At the present moment the utilisation of electric energy for the production of light is the one most prominently before the public mind. All the large cities in Europe and America have made progress, more or less, in the completion of conductor system, which make possible the public distribution of electric current and the sale of electric power. The very conception of an electric central station is not much more than ten years old, and yet before the close of this century the electric engineer will have made it so familiar a fact that it will cease to excite the smallest surprise. Electric locomotion has passed—at least in America—out of the region of an interesting lecture-subject into the domain of commonplace realities, and there are not wanting indications that this department alone is one of undreamt-of possibilities of development. The Institution whose members represent the active agents in our own country in the production of these tremendous transformations of the conditions of society, is one whose existence is not only a necessity but a growing one. The exchange of experience, the collection of information, and the stimulation of thought brought about by the existence of a corporate union between the members of a scientific profession is valuable and essential, and the practically important and useful results which can be brought about by the wise and careful guidance of such an Institution receives increasing illustration. It will achieve this, however, just in proportion as it keeps in touch with the practical necessities of its practical members. A little too much soaring into regions of theoretical science, and occupation of time on matters which are outside

Digitized by Google

the range of actual electrical engineering, will result in reduced usefulness and power; but a ready and energetic action in dealing with all questions which affect this ever-increasing public use of electricity will tell inevitably in increasing the extension of electrical enterprise and its own utility. The INSTITUTION OF ELECTRICAL ENGINEERS has already been able, in the first year of its existance as such, to give effect to the consensus of feeling among its members on some important practical matters, and there is much that it may do in this way, whilst still preserving the status of a professional Society. In the collection and diffusion of information, it has a wide field of work open to it, and there is, perhaps, no more useful mode of performing work of this character than by the delivery from time to time of Lectures on special practical subjects by the most authoritative persons in their particular departments. We call to mind in this connection the entirely admirable Lectures of this kind arranged by the INSTITUTION OF CIVIL ENGINEERS in 1882, in which the leading men in particular branches of knowledge expounded some subject of highly practical interest. One thing which greatly aids in adding interest to Papers or Lectures is the experimental illustration of them. The Chemical Society have, we believe, a laboratory in connection with their meeting room, in which experimental illustration can be prepared. Ought we not to look forward to a time when the INSTITUTION OF ELECTRICAL ENGINEERS will have an electrical laboratory of their own, or at any rate the means of amply illustrating any of the Papers or Lectures read before them which require it or admit of it? These and all other details of development will arrive in time, and as they are needed. Sufficient for the present, that the Institution is, as the PREMIER remarked, "weaned," and that the recognition of the status and the work of the Electrical Engineer has been prominently thereby advanced. It will be maintained only, however, by the sober success of the undertakings guided by him. We have passed through the stage of excited public imagination, and a necessary corresponding reaction concerning the problems of public use of electricity, and are now freed from the restrictions which an immature legislation cast about the electrical industry. The field of operation lies widely open for all wise and skilful development of solid invention, and although there is an unlimited possibility of failure when work of an important nature is undertaken by ill-informed or ill-advised individuals, yet the way, at the same time, is prepared for conspicuous triumphs when capital and energy are directed by competent and cautious Electrical Engineers.

DINNER OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The first annual dinner of the above Institution was held on Monday night at the Criterion Restaurant, under the presidency of Sir William Thomson, the guest of the evening being the Prime Minister. Amongst the other gentlemen present were the following:—Sir F. Abel, Sir James Anderson, Sir F. Bramwell, Sir J. Coode, Sir J. Kitson, Sir H. Mance, Major Marindin, R.E.; Sir R. Rawlinson, Sir D. Salomons, Mr. Justice Stirling, Sir G. G. Stokes, Mr. Courtenay Boyle, Prof. W. G. Adams, Mr. Albright, Mr. Alabaster, Mr. Andersen, Dr. W. Anderson, Mr. Andrews, Dr. Baur, Mr. Beaumont, Mr. Bidwell, Mr. Binswanger, Dr. Borns, Mr. Bottomley, Mr. Bright, Major Cardew, R.E.; Mr. Carpenter, Mr. Clark, Mr. Cockburn, Mr. Cousens, Staff-Com. Creak, R.N.; Mr. Crompton, Mr. Crowe, Mr. Down, Mr. Dowson, Mr. Drake, Mr. Erskine, Mr. Esson, Prof. Fleming, Dr. Fison, Prof. Forbes, Mr. Forrest, Prof. Foster, Mr. Garcke, Mr. Geipel, Mr. Gisbourne, Dr. Gladstone, Mr. Gordon, Mr. Gorham, Mr. Graves, Mr. Gray, Mr. Guy, Mr. Heaviside, Mr. Hedges, Mr. Higgins, Capt. Holden, R.A.; Mr. Holmes, Mr. Hookham, Dr. Hopkinson, Prof. Hughes, Mr. Kapp, Mr. Kempe, Mr. King, Mr. Laister, Mr. Manville, Mr. Massey, Mr. Mavor, Mr. Moulton, Mr. Muirhead, Major Flood Page, Mr. Pell, Prof. Perry, Mr. Phillips, Mr. Preece, Mr. N. Prentice, Mr. Price, Mr. Pritchett, Mr. Raworth, Mr. Rawson, Mr. Reckenzaun, Prof. Reinold, Capt. Sankey, R.E.; Mr. Schanschieff, Mr. A. F. Scott, Mr. Ronald Scott, Mr. Sennett, Mr. Sharp, Mr. Shoolbred, Mr. Siemens, Mr. Slater, Mr. A. T. Snell, Mr. Spagnoletti, Mr. Stroh, Mr. Swan, Mr. Swinton, Mr. Timmis, Mr. Truman, Mr. Varley, Mr. Von Buch, Mr. Wallace, Dr. Walmesley, Mr. F. H. Webb, Major-General Webber, Dr. Wedgewood, Capt. Wharton, R.N., Mr. Wharton,

The PRESIDENT, in proposing the health of Her Majesty the Queen, said that the Institution of Electrical Engineers had every reason to appreciate very highly the reign of Queen Victoria (cheers). During the lifetime of Her Gracious Majesty electricity had become a science. The earliest discoveries, one might say, took place very nearly at the time of Her Majesty's birth, and electricity became a branch of engineering almost at the very moment when Her Majesty came to the throne. The prosperity which had attended her reign, from the beginning of it down to the present time, had been shared by all those professions upon which the prosperity of the country depended, most notably those which had led up to the existence of the Institution of Electrical Engineers. The toast would, he knew, be received with loving loyalty on the part of all those present (cheers).

The PRESIDENT next proposed the health of the Prince and Princess of Wales and the rest of the Royal Family. They were, he said, a very kindly family, and one which was thoroughly appreciated and admired throughout the whole of the British Dominions. They always devoted themselves to doing their duty to those around them, and on every occasion they sacrificed their own inclinations to the public good (cheers).

The next toast proposed by the President was that of the "Army, Navy, and Reserve Forces," which was coupled with the names of General Webber, C.B., and Captain Wharton, R.N. Sir WILLIAM THOMSON said that it seemed as if the forces of the Army and Navy and Reserve were destined to become more and more electrical (hear, hear). By means of the telegraphists attached to the Royal Engineers the land forces had long been connected with electricity. Thirty years ago the first duty of an electrician was to make himself a sailor, because at that time the great part of electrical work consisted in the laying of submarine cables; but now electrical science was called into use in both branches of the service, and, in fact, formed the foundation of the scientific knowledge of the officers in those branches. At the present moment there were no less than 70 officers of Her Majesty's forces who were members of the institution, and, in fact, every midshipman, however good a cricketer he might be, however good in the boats, or in other branches of athletics, must now be an electrician, in order to carry out the various duties which he was called upon to perform (hear, hear).

Major-General WEBBER, in responding on behalf of the Army, said that of all the applications of electrical science there was none perhaps which interested him more than the electric telegraph as applied to the art of war. Nearly a quarter of a century had elapsed since he first saw the electric telegraph used in the campaign of 1866, in the results of which the art of telegraphy played so important a part, and when there was a line of telegraph extending from the Prussian army right through to Berlin. What would have happened, he asked, on that memorable afternoon of Waterloo if Blucher and Wellington had been in telegraphic communication? The advantages of having such a means of communication had been demonstrated in every small war during recent years in which the telegraphists of the Royal Engineers had played so important a part

Captain WHARTON, in responding for the Navy, referred to the great influence which electrical science had had in the development of the British Navy. Perhaps the most important point to mention was the use of electric search lights, without which no ironclad could guard against the attacks of torpedo boats. Sir William Thomson had done good service to the Navy, not only in regard to the laying of electric cables, but by his admirable compass, and the sounding apparatus, which were now so largely used on board ships (hear, hear).

Sir WILLIAM THOMSON (in proposing the next toast, that of "Her Majesty's Ministers") said: I have only to mention the name which I am about to couple with this toast to evoke those feelings which are so strongly felt by us in respect of what we owe to Her Majesty's Ministers. How is it that we can go on and live happily, and practice our professions and cultivate our sciences in peace? It is through the action of Her Majesty's Government. Good government produces happiness and prosperity to the whole nation, and incidentally to the scientific and engineering part of the nation, by enabling us to carry on our investigations and that great public work which is the object of the existence of such an Institution as the Institution of Electrical Engineers. Most of us think we have done our duty to the country when we have given our votes and paid our taxes, if we are taxpayers. But what a very small part is that as compared with the highest kind of work which is performed by those men whom the constituencies honour by electing them to be their members of Parliament! We owe all the happiness under which we live to those who do the work of the nation for us. Every member of the Government has some private occupation, which, as men of the highest

Digitized by Google

education and the highest ability everyone of them, they would wish to be doing, but which they have given up in order to perform their daily work as Ministers. And what must we, as electricians, think of the man who gives up electricity to serve in that way—a man who might be working in all the beauties of electrical science: following them, reading about them, investigating them, and making discoveries in them—were it not that a higher duty called upon him to take up the work of the State in the interests of the nation (cheers)? Gentlemen, as being one of ourselves in the sense of being a scientific electrician and an electrical engineer, I feel that we must all appreciate the honour which Lord Salisbury has done us in being present at this our first dinner at the end of the first year of the Institution of Electrical Engineers. Gentlemen, I ask you to drink to the health of Her Majesty's Ministers, coupled with the name of Lord Salisbury (great cheering).

The MARQUIS OF SALISBURY (who met with an enthusiastic reception) said: Sir William Thomson and gentlemen, I have to thank you on behalf of my colleagues and myself for the exceedingly hearty reception that you have given to the kind words in which Sir William Thomson has proposed this toast. I do not feel that I can accept the guise in which he has put my name forward. On the contrary, though recognising, as every individual must do, and as I have special reason to recognise, the enormous benefits which electrical science confers upon mankind, I feel that I have reason to apologise for my appearance in this assembly; and when I look around at the number of learned and distinguished men here present to-night, I feel rather in the position of a profane person who has got inside the Eleusinian mysteries (laughter). I have an excuse that the learned gentlemen, General Webber and Captain Wharton, who have replied on behalf of the Army and Navy, were able to show many particulars in which their special professional vocation was sustained and pushed forward by the discoveries of electric science, but I will venture to say that there is no department in the Government so profoundly indebted to the discoveries of those who have made this science as the Foreign Office, with which I have the honour to be connected (hear, hear). I may say that we positively exist by virtue of the electric telegraph. The whole work of all the Chanceries in Europe is now practically conducted by the light of that great science, which is not so old as the century in which we live. And there is a strange feeling that often you have communicated constantly and frequently day by day with men whose innermost thoughts you may know by the telegraph, but whose faces you have never seen (hear, hear). It is something more than a mere departmental effect which these great discoveries have had upon the governments of the world. I have often thought that if history were more philosophically written, instead of being divided according to the domination of the particular dynasties or the supremacy of particular races, it would be cut off into the compartments indicated by the influence of particular discoveries upon the destinies of mankind. Speaking only of these modern times, you would have an epoch marked by the discovery of gunpowder, an epoch marked by the discovery of the printing press, an epoch marked by the discovery of the steam-engine; and these discoveries have had an influence infinitely more powerful, not only upon the large collective destinies, but upon the daily life and experience of multitudes of human beings, than even the careers of the greatest conquerors, or the services of the greatest statesmen (cheers). In that list, which our ignorance of ancient history in its essential character forbids us to make as long as no doubt it might be made, the last competitor for notice, and not the least, would be the science of electricity. I think the historian of the future, when he looks back, will recognise that there has been a larger influence upon the destinies of mankind exercised by this strange and fascinating discovery than even by the discovery of the steam-engine itself—(hear, hear)—because it is a discovery which operates so immediately upon the moral and intellectual nature and action of mankind. The electric telegraph has achieved this great and paradoxical result: it has, as it were, assembled all mankind upon one great plane, where they can see everything that is done, and hear everything that is said, and judge of every policy that is pursued at the very moment those events take place. And you have by the action of the electric telegraph combined together almost at one moment, and acting at one moment upon the agencies which govern mankind, the opinions of the whole of the intelligent world with respect to everything that is passing at that time upon the face of the globe. It is a phenomenon to which nothing in the history of our planet up to this time presents anything equal or similar, and it is an effect and operation of which the intensity and power increase year by year. When you ask what is the effect of the electric telegraph upon the condition of mankind, I would ask you to think what is the most conspicuous feature in the politics of our time, that occupies the thoughts of every statesman, and that places the whole future of the civilised world in a condition of doubt and question? It is the existence of those gigantic armies held in leash by the various governments of the world, whose tremendous power may be a guarantee for the happiness of mankind and the maintenance of civilisation, but which on the other side hold in their hands powers of destruction which are almost equal to the task of levelling civilisation with the ground. And what gives those armies their power? What enables them to exist? By what power is it that one single will can control these vast millions of men, and direct their destructive energies at one moment upon one point? What is the condition of simultaneous direction and simultaneous action which alone gives to these vast armies their vast power? It is nothing else than the electric telegraph (hear, hear). And it is from that small discovery, worked out by a few distinguished men in their laboratories upon experiments of an apparently trivial character on matter, and with instruments not in the first instance of a very recondite description. It is on that discovery that the huge belligerent power of modern states which marks off our epoch of history from all that has gone before it, must be held by anyone who investigates into the causes of things absolutely to depend. I would venture to hope that this is not all in its great effect upon the history and government of our race that electricity may achieve. Whether it is so for good or evil in the main it must be for the future to determine. We only know that the effect, whatever it is, will be gigantic. But in the latter half of the short life of this hitherto young science another aspect of it has been developed, an aspect which I cannot help hoping may be connected with great benefits to the vast community of industrious and labouring men—I mean for the distribution of power, of which electricity has given such a splendid instance (hear, hear.) The event of the last century was the discovery of the steam-engine; but the nature of the steam-engine was such that the force which it produced could only act in its own immediate neighbourhood, and therefore those who were to utilise that force and translate it into practical work were compelled to gather round the steam-engine in vast factories, in great manufacturing towns, in great establishments where men were collected together in unnatural and often unwholesome aggregation. Now an agent has been discovered by which the force of the steam-engine, stiff, confined to its own centre, can be carried along far away from its original source to distances which are already great, and which science promises to make more considerable still (hear, hear). I do not despair of the result that this distribution of force may scatter those aggregations of humanity, which, I think, it is not one of the highest merits of the discovery of the steam engine to have produced (hear, hear). If ever it shall happen that in the house of the artisan you can turn on power as now you can turn on gas (and there is nothing in the essence of the problem, there is nothing in the facts of the science, as we know them, that shall prevent such a consummation from taking place)—that distribution of power should be so organised—you will then see men and women able to pursue in their own houses many industries which now require the aggregation of the factory. You may, above all, see women and children pursue those industries without that disruption of the family which is one of the most unhappy results of the present requirements of the industries; and if ever that result shall come from the discoveries of Oersted and Faraday, you may say that they have done more than merely add to the physical force of mankind. They have done much to sustain that unity, that integrity of the family, upon which rests the moral hopes of our race, and the strength of the community to which we belong (hear, hear).

Gentlemen, these are some of the thoughts which electricity suggests to one of my trade. Pardon me if I have wandred into what may seem to be speculative and unfamiliar fields. But, after all, the point of view from which we must admire the splendid additions to our knowledge which the scientific men of the world, and especially of England, during this century have made, is that they have enabled mankind to be more happy, to be more contented, and therefore to be more moral (prolonged cheering).

Sir FREDERICK ABEL, in proposing the toast of "The Learned Societies," said: We members of the Institution of Electrical Engineers do not aspire to count ourselves "learned," inasmuch as we do not, as a body, attempt to pursue science purely for its own sake; but I believe there exists no other body which so thoroughly and fully appreciates the work in this direction that is accomplished by the brethren of the learned societies. I feel sure that you will desire to associate with this toast of "The Learned Societies" the name of the man who, among scientific workers, has especially distinguished himself by his versatility of power, by his indomitable industry, by his encouragement of those who engage in the work of science for science sake, and by his always ready help to those who work for the application of science to practical purposes. I give you, my lord and gentlemen, 'The Learned Societies," and I couple with this toast the name of Sir Gabriel Stokes, the President of the Royal Society (cheers).

Sir GABRIEL STOKES, in responding, said: My Lord Salisbury and gentlemen, I rise to return you thanks for that toast with which Sir Frederick Abel has done me the honour of coupling my name. For a long time the Royal Society remained the only scientific society, and we took under consideration all branches of science. But as science grew, it was found expedient to establish special societies for special departments. Nevertheless, we look on those societies with a feeling of parental affection, and we retain so far our old constitution that we receive Papers on all subjects of science. When I came into the room and saw your programme of toasts I did not know to which of the two categories—to the learned societies or the professional societies—you considered yourselves to belong. If we look at the great achievements for supplying the needs of daily life which have been effected at the present day through the agency of electricity one would say that this Society belongs to the professional societies. In this very room we have an example of that beautiful electric light which has now become tolerably common, and of which, in all probability, before very long we shall see a good deal more in London. And then, again, I need not refer to the subjects which have been already so amply dwelt upon by Lord Salisbury and others—the total revolution which has been brought about by the introduction of the electric light. Nowadays the whole earth resembles, in a measure, one of our own bodies. The electric wires represent the nerves, and messages are conveyed from the most distant regions to the central place of government, just as in our bodies, where sensations are conveyed to the sensorium. And then, again, the orders are issued. Now, if these applications were alone considered, one would say that the Institution of Electrical Engineers is a professional society; but we must also look at the origin of the Society, and at the manner in which these remarkable results have been accomplished since the first discoveries. When I think of the applications of electricity, my mind cannot help going back to that laboratory in Albemarle-street, where the great Faraday made so many important discoveries which have borne fruit in those applications with which we are now so familiar; and to come to a more recent time, I cannot help remembering how deeply your President went into the mathematical theory of the electrical actions which take place in a submarine cable, and how the success of that first

Digitized by Google

great experiment of spanning the Atlantic was largely indebted to him for his investigations (hear, hear). Therefore, I cannot look on this Society simply as a professional society. I must consider that it forms the connecting link, being at the same time both scientific and professional (cheers).

Mr. LATIMER CLARK (in proposing the toast of "The Professional Societies,") said: My lord and gentlemen, I am entrusted with the toast of "The Professional Societies," and I shall have the pleasure of coupling with that toast the name of Sir John Coode. I have given due consideration to the question, and I say with all deliberation that a more important toast could not well be proposed. The members of the professional societies comprise among them a large proportion of the men who have really given to the world its present form and character. They comprise the various classes of engineers—the civil engineers, the mechanical engineers, and the electrical engineers; they comprise also the builders of ships and the men who have produced the great features of civilisation as we have it to-day. In doing this they have so changed the face of the world that we begin to feel almost already that it is getting a little inconveniently small for us; but at the same time they have added very greatly to the prosperity of this country—and of all countries, in fact; and they have added to the lustre of the reign of Queen Victoria. They have created a veritable epoch in the history of civilisation which will never be forgotten. And whatever may be the fate of this little island in all future time, however distant, this will be pointed to as the period of origin of some of the greatest inventions which have marked the progress of civilisation. Now, the members of the professional societies are not politicians, and have no political bias; but I think they have been a little unfairly treated by politicians. I have always felt that politicians, or at all events some of them, have claimed to themselves many of the merits and advantages which have really been earned for them by the professional societies and their members. They have for a long succession of years pushed forward in season and out of season the claim that to them have been owing the great bursts of prosperity which have from time to time marked the course of the last 30 years, so that it has at last come to be stated as a matter of creed, of belief, that all the great blessings that have been showered upon the world and upon society by professional men have been due to the action of these politicians (hear, hear), and that they have had a most profound influence upon the present condition of society and upon the present belief of those now living.

I am extremely pleased to find that this toast will be responded to by the President of the Institution of Civil Engineers, and I am sure you will be pleased as well, because it will give us an opportunity of testifying how much we appreciate the assistance we have always received from that Institution, and the kindness they have always shown to us. We have been permitted from the first to occupy their magnificent room and theatre, and really to disport ourselves there as if we were the proprietors (hear, hear). I hope they have never seen reason to regret it. I do hope that, whatever may be our fate, the friendly relations and cordial feelings which have existed up to the present time between these two sisters will be strengthened in the future so long as these convivial meetings last (hear hear). The toast I have to propose to you is, "The Success and Prosperity of the Professional Societies, accompanied with the name of the President of the Institution of Civil Engineers" (cheers).

Sir JOHN COODE (in responding) said: Sir William Thomson, my Lord Salisbury, and gentlemen, I think if I rightly interpret what fell from Sir Gabriel Stokes, he has a feeling, in common with myself, that the learned and the professional societies might very well have been coupled together; in fact, to separate them appears to me to be very much like separating man and wife, because the inter-dependence of the one upon the other is of the most intimate kind. I am pleased to find that the civil engineers did in the younger days of the Electrical Institution extend to them a helping hand when they were only just fairly out of their swaddling clothes (hear, hear). Well, we did that with the utmost pleasure, and we have only done to electrical engineers what we have done to other kindred societies. We have regarded ourselves—I hope I may say so without vanity—as the parent of the professional societies: certainly in the case of those of an engineering character; and, whatever their character may be, we shall always be pleased to act to other societies of an engineering kind in the same manner as we have done towards the Institution of Electrical Engineers (cheers).

The MARQUIS of SALISBURY (in proposing the toast of "The Institution of Electrical Engineers") said: Sir William Thomson and gentlemen—As your toastmaster has told you, the toast of the evening has been confided to my charge, though I feel that the lateness of the hour will prevent me from doing it that justice which it deserves. The toast is "The Institution of Electrical Engineers." This is no doubt a very interesting moment in the life of the Institution of Electrical Engineers. It is, I understand, their first convivial meeting; and an Institution which dines for the first time may be looked upon as a child that has just been weaned (laughter.) The simile is not so inapt, because it is just taking to its bottle (great laughter). All that I could say in its behalf would be pale compared to the consciousness of its merits which must inhabit the minds of all its authors, and they must feel that I should be profaning a sacred subject if I were to attempt to go into those technical details by which alone its merits could be sufficiently illustrated. But I feel that a paper which has been put into my hands will, at all events, illustrate what great need there was for an institution of this kind, and what splendid possibilities in the future its destiny discloses. I am told that this Institution contains nearly 1,700 members, although it is not a year old, and that it represents the science of electricity, its application to telegraphy—land and marine—to telephony, to electric lighting, to transmission of power, locomotion by electric railways, tramways, and omnibuses. Now this vigorous infant is obviously the child of the Institution, represented by Sir John Coode, who has just sat down. He may look upon himself, when I read this paper, as the possible grandfather of a tremendous offspring (laughter and cheers), for it is evident that this Institution will not remain barren. It will increase by what I believe physicists call gemmation, and there will be cut off from it from time to time new institutions, representing each one of the copious subjects which I have read to you. There is evidently, therefore, a great destiny for it in the future; but I think that those who have founded it have been wise not to commence their process of sub-division too soon. It is very well that these various kindred societies should remain together for some time longer, and that the cordiality which distinguishes the learned societies should be encouraged in the future by the close association and companionship of their early days. It is, indeed, a splendid sphere of activity which such a list as this points out for the science of electricity and for those who have to give it practical effect. It is a splendid career which it opens to all those to whom the maintenance and application of this science is confided (cheers). Whenever I have been—as I occasionally have the privilege of doing—in an assemblage of scientific men, I cannot help comparing, with a melancholy feeling, the endurance and permanence, and almost eternal existence, of the work with the transitory work of the profession to which I belong. Politicians may do good, or they may do harm; they hardly know what result destiny will give to their actions; they do not know how the Divinity will shape their ends which they are trying to rough-hew. They cannot so measure the causes which act on the formation of human events and human history as to judge of the permanence or transcience of their work. With you it is otherwise. Every brick that you add to this great pile will last as long as human consciousness endures. Every atom which an electrician brings to the great science which he cultivates will remain there doing its work right to the end, as long as the intellect of man exists by which the science can be applied. It is therefore a great destiny which your Institution has before it, and a great responsibility which lies upon it.

In asking you to drink to the good fortune and good health of this Institution, I will ask you also to couple with it the name of one who, more than any other living man, has given to electricity its power and its fame (loud cheers). In asking you to drink to it in conjunction with the name of Sir William Thomson, I add the name of one whose marvellous investigations, whose extraordinary inventions and singular accuracy, and the practical character of whose science has been felt by every man present, in whatever department of science he may be, in the practical carrying out of his work (hear, hear). If Faraday and Wheatstone have begun this work, the historian will record that no stronger hand ever existed to carry on the sacred flame to further generations than the hand of the distinguished and gifted man who has been your President this evening. I propose to you the toast of "The Institution of Electrical Engineers," coupled with the name of Sir William Thomson (loud cheering).

Sir WILLIAM THOMSON (who, on rising to respond, was received with loud and continued cheering) said: My Lord Salisbury and gentlemen—After the noble words in which we have just heard the domain of the Institution of Electrical Engineers described, I feel that, as the spokesman for that Institution, my voice is almost speechless, and no words from me will be worthy of the occasion.

As President of the Institution of Electrical Engineers, I must say at this its first convivial meeting, that its existence is owing to a marvellous succession of scientific discoveries, followed speedily by the reduction of those discoveries into practical form for the good of mankind. In having the honour of proposing the health of Her Majesty the Queen at an earlier part of our proceedings this evening, I did feel that the reign of Queen Victoria and the history of electricity as a branch of an applied science were synchronous, and synchronous to a most unique degree. The science of electricity is as old as human learning. In the remotest times Greek and Arabian philosophers give us something of our present electrical knowledge. Last century was full of work in pure electrical science, much of which we are going back to now we are finding out things which go to the very depths and subtleties of electrical science. But what is the most remarkable in the history of the subject is the tremendous development that it has received since the year 1819. The idea of the possibility of the conjunction of the words "electrical" and "engineering" did not exist, I think I may say, before the year 1837, when the electric telegraph came into existence. I do not say that the telegraph was invented by Wheatstone, but I do say that by the labours of Wheatstone and Cooke the electric telegraph became a practical servant for the use of man. Though the term electrical-engineering might have been in existence then, it was many years before it came into general use.

One very remarkable piece of work that we are likely to think of, especially in these last weeks of this year, during which we deplore the loss of one of the greatest workers in electrical science and its practical application that the world has ever seen, is the work of Joule. The great scientific discoveries of Faraday, which were prepared, almost, you might say, in his laboratory by their author for the purpose of allowing others to turn them to account for the good of man, had been going on for about fifteen years, when a young man took up the subject with a profound and penetrating genius most rare in any branch of human study, and perceived relations with mechanical power which had never been suspected—not even suspected by Faraday, although Faraday in our country, and Henry in America, had given all the principles upon which these applications depended. Joule saw the direct relation between electricity and force, and it is most remarkable for us to think that his was the very first determination of the mechanical equivalent with an electrical measurement (hear, hear). Joule's communication to the British Association when it met in Cork in the year, if I remember rightly, 1841, pointed out for the first time the distinct mechanical relation between electrical phenomena and mechanical. Joule was not a mere visionary who saw something in the air and admired it, threw a halo around it and left, but he pursued it to the

Digitized by Google

utmost practical point of work; and he it was who determined the mechanical equivalent of heat, and who explained what are known as magneto-electric effects at that never-to-be-forgotten meeting of the British Association in Ireland. His next determination was a mechanical one; his third one a mechanical one still; and his determination, though slightly altering the principle, thoroughly determined the results of his previous work, both in electricity and mechanical action, and led to that new development of thermo-dynamics which will be looked back upon in future centuries as the crowning scientific work of the nineteenth century. I do not say that it is all due to Joule; but I say that Joule's dogged resolution to go on till he had determined it, and his resulting determination of the mechanical equivalent, is one of a peak of mountains which will be looked back upon and admired more the further we are from it as one of the greatest scientific movements of the present century. For the Institution of Electrical Engineers, it is most interesting to think that one of our most important fundamental electrical elements, the purely electrical determination of the units of resistance—the British Association unit—should be called at the suggestion of one who is here with us to-night (Mr. Latimer Clark), and his colleague (Sir Charles Bright), whom we have lost many years ago, first of all the "ohmad," and soon after the "ohm." Now it is most remarkable to find that while that was determined electrically in the first place by a Committee of the British Association, by a purely mechanical method, a determination amounting to $1\frac{6}{10}$ths per cent. was first discovered, although not thoroughly recognised as being discovered, by Joule's mechanical measurement. It was Joule's mechanical measurement that first corrected the British Association unit and gave the true ohm. The true ohm was also ascertained by a second electrical measurement, chiefly by the measurement of Lord Rayleigh. Though many other measurements give nearly the same result, Lord Rayleigh's measurement gave that which we know to be the most accurate result; and it is wonderful to think that that agreed with the most minute accuracy with the purely mechanical determination of Joule. I think that at this, the first dinner of the Institution of Electrical Engineers, it is well that we should consider the memory of Joule as one of the most fundamental memories in the eventful history of electrical science, from the time when electricity was a science not devoted to mechanical purposes to the present time, when it has developed into being a branch of engineering (hear, hear).

Now this Institution of Electrical Engineers, which is nearly at the end of its first year, and which is now having its first annual dinner, I hope may go on and attract the sympathy of the world and place itself in harmony with the dining, if not with the scientific world in general. This Institution does not come into existence like Minerva, complete in its panoply, and standing forth before the world grand and beautiful as you see it to-day. It began with an Institution of Telegraph Engineers in 1870, 19 years ago. I should not like to be obliged to undergo an examination on the history it has had during those 19 years; but it was growing up, and destined by Providence to become the greater Institution of Electrical Engineers that we have to-day.

Now having said this, I need scarcely say that I feel profoundly thankful. At the same time, I cannot help a certain feeling of pride at being allowed to be President of the Institution of Electrical Engineers on this occasion. I thank you for the great honour you have done me in choosing me as your first President, and for the kind manner in which you have received my name and connection with the toast which Lord Salisbury has just put before you this evening (great cheering).

TRAIN ELECTRIC LIGHTING.*

BY CHARLES SELDEN.

Some months since your committee on Papers to be read at this meeting assigned to me the subject of "Train Electric Lighting," since which time I have been availing myself of every opportunity when coming into contact either with systems in use, or parties exploiting them, to glean all the information possible.

Whenever I attempted to get down to figures with any of these exploiters or promoters, I was always met with a general answer, which was of no use whatever to us who contemplated the introduction of such a system upon our roads. By travelling first, and carefully noting the devices employed, and then conferring with manufacturers, I became conversant with what ordinarily would be the cost of such things as were in sight, and I am now able to offer you, for probably the first time that it has been done, the *maximum figures* upon at least one system. This is the system employed by the Pullman Company, and which I will designate below as System No. 1, and from this we can deduce the cost of one other (System No. 2). I made several trips on their trains and observed the working of this system in all its particulars, spending the better part of three nights' run in watching, both in the baggage car as well as others, and it was very satisfactory indeed, the light being brilliant and everything that could be desired. I have examined the Boston and Albany system partially, but as that is purely a storage battery affair, I cannot report results in figures until facts are obtainable upon which I can stand and feel assured that the figures which I give will at least not represent a cost less than we would find if put into practice; the figures I herewith give you are therefore *maximum*. In practice this subject can well be considered under the head of three systems:—1. Lighting cars by the joint use of dynamo and storage battery; 2. Lighting cars by means of direct current from the dynamo; 3. Lighting cars by means of a charged storage battery. System No. 1 is in use by the Pullman Palace Car Company upon its limited New York and Chicago trains, the vestibuled trains of the Atchison, Topeka, and Santa Fé Railroad Company, and others.

Wiring.—The main wires or leads are covered in a moulding along the top of the car, and branches therefrom are either dropped down through the air tube of the ordinary lamp (where centre suspension is desired) or are led through the panel between the ventilators of the car, where it is desirable to have a bracket. On top of this moulding is placed another, and then all of this moulding is tinned over and securely soldered, so that there is no leakage into the car, and the wires are fully protected. They are also free, in a great measure, from any movement by reason of oscillation or jarring, and hence the chances for abrasion of the insulation are reduced to a minimum, while at the same time they can be got at much more easily than if they were placed between the roof and the head-lining. The average cost per car, fitted with the best wire, is about 100dols. This includes labour.

Engine and Dynamo.—A Brotherhood engine, directly connected with an Eickemeyer dynamo, both of them being upon the same cast-iron bed-plate, is placed within a lattice-work inclosure at the forward end of the baggage car, occupying a corner between the end door and the side door. Ordinarily this space is $3\frac{1}{2}$ft. by $5\frac{1}{2}$ft. This engine is fed by steam from the locomotive, the steam gauge within the baggage car usually showing a pressure of 60 pounds, of which 15 is exhausted through the pipe for heating the train. The dynamo has an electromotive force of 68 volts, and has 60 amperes at 800 revolutions per minute. It should be understood that at 900 revolutions the same machine would give you 80 volts and 80 amperes. A good dynamo of this capacity will give plenty of light for 120 lamps throughout the train, and is considered an economical one, for the reason that it has margin enough to serve a longer train than usually carried, so as to meet emergencies should they arise.

Storage Battery.—Each car carries in a box, securely fastened to the bottom of the car, 32 storage cells, and under the system of distribution this storage battery is partly in use at all times, furnishing, when the dynamo is running, 30 per cent. of the power given to the lamps, and, when the dynamo is not running, furnishing all the power. The weight complete of the battery and its boxes is 1,300lb. per car. During the day, or at other times, when the lights are not in use, the dynamo is run a number of hours charging these storage batteries, so that it is unnecessary to remove them from their location under the cars for a long term, dependent ordinarily upon whether or not they have been in a wreck, or by long use the plates have become buckled, when, of course, it is necessary to remove such plates and put the battery in good condition. It is claimed that with this system the storage batteries last longer than where they are subject to removal for recharging at the end of each trip.

This system, as in vogue, has an attendant costing 90dols. per month and board while on the train, who is more or less experienced in electric lighting; and at terminal stations—that is to say, Chicago and New York—an expert ordinarily inspects the condition of the electric service prior to the train leaving, and at the station at Pullman they have also an electric light plant, which is utilised for storing electricity for their cars placed in the shop and which are about to start out on the road.

The arrangement of the engine is so concise that I do not see why the baggage master should not be able to run it, after a little coaching, without any other attendant. For instance, if we have a gauge for steam from the engine with a notice under it that "This gauge should stand at 65," and under the ammeter, "This gauge should stand at 63," and under the tachometer, "This gauge should stand at 800," it seems to me that any one with the least bit of common sense and a little bit of drilling, would surely be able to run the plant, for (as can be explained to him) if with cock fully open steam should get below the point which you mark and call his attention to, he is to call on the enginemen for more steam. If the revolutions fall below 800 it would at once call his attention to the steam gauge, and if the voltmeter or the ammeter should show out of proportion, the test lamp in the baggage car or the other lamps in the baggage car would become dim, thus calling his attention, even though he were otherwise engaged. If the enginemen cannot give him more steam, then there is but one thing for him to do, namely, cut off the dynamo entirely and fall back upon the storage battery for the light for the train. This, I think, would complete all I have to say at present upon System No. 1, the expense of which I show in full later on in this Paper.

The system of lighting direct from a dynamo upon a train, without the auxiliary help of a storage battery (System No. 2), is not in use; but I confess that I do not see why it would not be a good thing to do and save the expense, both in plant and the depreciation of the storage battery. There is an objection, of course, that

* Abstract of Paper read before the eighth annual meeting at Washington, D.C., of the Association of Railway Telegraph Superintendents.

Digitized by Google

in case of any failure, either in connections, engine, or dynamo, the lights would go out, leaving the train in darkness. This, however, could be obviated, I think, by keeping one coach candle or one lamp in each car lit; it is necessary to carry lamps or candles anyhow for emergencies.

System No. 3 is employed by the Pennsylvania Railroad Company, the Boston and Albany, and some others. I have been unable as yet to get any figures as to the cost. This system consists in merely placing upon each car a number of cells of storage battery (the cost of each cell ranging from $9 to $12), which are usually charged at the terminal points, the batteries then being trucked to the cars and placed therein, running one trip and then being trucked out for recharge. The Pennsylvania Company use a small number of cells (12 to the car) and a low voltage lamp, namely, 23 volts. They claim to get 16 candle-power to each lamp, but I hardly think that they do this. The lamps that I have seen seem to me to be of less candle-power, and they seem to use a smaller number than are necessary to properly light the car for reading. Ordinarily they carry seven lights in the body of the car at 23 volts, one in the smoking-room of 22, and one in each hallway or approach of 24 volts, making in all 10 lights to the car. With the Pennsylvania Company, at the time of my examinations, these lights were employed only in their parlour cars. The best report I could get from that Company was to the effect that they really do not know what the lights cost them, that it had never been figured down in a fine way. They have power and electric light stations at Jersey City, and they use a portion of that power for storing current during the daytime, while at the same time the same power was employed at night in lighting their yards, &c., so that it was a hard matter to get at; but they had determined that, while the light was a little more expensive than oil, at the same time it was cheaper than gas as used by them formerly, which was placed in retorts underneath the car.

Referring to the figures that follow, the prices of engines and dynamos can be "shaded," while the depreciation noted may in some instances be greater than is shown, or in others less. Of course the figures given do not include the cost of steam which runs the engine in the baggage car; but on that subject it was reported to me as follows:—The officer of the Pennsylvania Railroad Company, who has such matters in charge, states that the difference in the consumption of coal upon their locomotives (and this, of course, is the proper source from which 1 figure) is so slight as between those that are feeding dynamo engines and those that are not doing so, as to make no difference practically, and it has not affected the premiums which are given to firemen upon their saving of coal. I find a difference in the opinion of the enginemen upon these trains, some saying that they do not notice, particularly, the loss of steam used by the dynamo engine, or in heating the train; others again complain that they always feel it.

Following is the cost per sleeping and dining car equipped with System No. 1, having Eickemeyer dynamo and Brotherhood engine, including depreciation and interest on plant at 5 per cent., *not* including salary of attendant.

SLEEPER.

Articles required.	No.	Cost each.	Total.	Depreciation per cent.	Total.	Interest at 5 %.
Battery cells ...	32	$9.00	$288.00	16½	$47.52	$14.40
Wiring.....	1	100.00	100.00	.....	.....	5.00
Lamps.....	26	.75	19.50	700	135.50	6.83
Lamp-sockets...	26	1.10	28.60	1	.29	1.43

Shades.....	26	.35	9.10	10	.91	.46
Elec. light arms.	26	1.15	29.90	.....	.....	1.50
Total	...	.....	$504.23	.....	$185.22	$31.07

DINING CAR.

Articles required.	No.	Cost each.	Total.	Depreciation.	Total.	Interest at 5 %.
Battery cells ...	32	$9.00	$288.00	16½	$47.52	$14.40
Wiring	1	100.00	100.00	.. ...	.....	5.00
Lamps	21	.75	15.75	700	110.25	5.52
Lamp sockets ...	21	1.10	23.10	1	.23	1.16
Cut-outs	1	.45	.45	.....	.....	.02
Switches	1	4.00	4.00	.....	.....	.20
Connections.....	1	20.00	20.00	.....	.....	1.00
Shade-holders ...	21	.18	3.76	.....	.....	.19
Shades	21	.35	7.35	10	.74	.37
Elec. light arms.	21	1.15	24.15	.....	.....	1.21
Total	...	.....	$486.58	.....	$158.74	$29.07

Upon the above basis a train would cost for 365 days of ten hours each on System No. 1, as follows:—

Car.	Lamps.	Depreciation.	Interest.
Baggage	5	$156.03	$93.19
Smoker (or day)	14	121.66	26.26
Day.....	14	121.66	26.26
Sleeper	26	185.22	31.07
Sleeper	26	185.22	31.07
Total	85	$769.79	$207.85

Or total as to equipment	$977.64
Add attendant at $90 per month	1,080.00
Total	$2,057.64
Or per day	$5.640
Per lamp, per day	.066
Per lamp, per hour	.006
Or for a baggage car, per day	.330
For a day car, per day	.920
For a sleeper, per day	1.720

System No. 2 would be as much cheaper than System No. 1 as the cost of battery and its depreciation would amount to. Either System, 1 or 2, without an attendant becomes still cheaper.

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 1st inst., Mr. W. G. Gregory read a Paper

"On a New Electric Radiation Meter."

The author observed that the usual method of detecting the radiations emitted by an electrical oscillation consists in observing the sparks produced across a small air-gap in a wire, either straight or bent into a circle. Quantitative measurements made in this manner must necessarily be extremely rough, the method of measurement consisting in observing the width of the air-gap, which is capable of adjustment by means of a micrometer screw.

Mr. Gregory's method consists in observing the elongation in a stretched wire, due to the rise in temperature produced by the currents induced in it by the rapidly varying field of force.

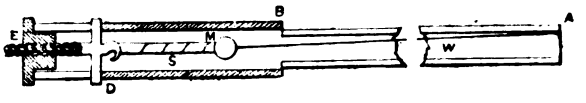

FIG. 1

The instrument, as shown in the diagram Fig. 1, consists of a long glass tube, A B, joined to a shorter piece of brass tubing, B D. Within is stretched a platinum wire, W, fastened to the glass tube at A, and to an Ayrton and Perry magnifying spring at M, at which point a mirror is attached in order to register the rotation by the reflection of a beam of light on to a scale. At E there is a screw for adjusting the tension. The brass tube is filed away in front of the mirror, so as to form a window, which is covered by a piece of plate glass. The object of the metal tube is to compensate the spring for general changes of temperature, and the glass serves the same purpose for the platinum wire.

The wire employed by the author was ·0086 cm. in diameter and 192 cm. in length. The spring, which had a length of about 25 cm., was made out of a narrow strip of very thin tinsel, by rolling it into a helical form, and then pulling it out in such a manner that it was free to untwist. This was effected by attaching the free end of the spring to a fine silk thread. It was then rolled between two hard surfaces, and again pulled out; and this process was repeated until at last it gave 10 complete rotations for an extension of one millimetre.

The mirror was a worked concave one, two-tenths of an inch in diameter, and gave a very good image of a wire on a scale at a distance of one metre. With an ordinary galvanometer scale there was no difficulty in reading with accuracy to a single division, which would correspond to an extension of ·000005 millimetres. The rise of temperature corresponding to this would be about ·003 of a degree centigrade. When the oscillator was at a distance of four metres a deflection of only one division was obtained, showing that the effect to be measured is an exceedingly small one.

The oscillator employed consisted of a pair of brass rods ·53 cm. in diameter, supported horizontally, and carrying zinc plates 40 sq. cm. in area, arranged to slide along the rods, so that the wave-length

Digitized by Google

could be altered at pleasure. The terminal knobs were 2 cm. in diameter, and the air-gap was about 2 or 3 mm. It was found that, during the experiments, one knob invariably became very hot, while the other remained cool, and it was the former which was the least blackened.

The induction coil used with the oscillator was 20 cm. long and 12 cm. in diameter, and it was worked by means of a tuning-fork contact-breaker, giving about 86 breaks a second. With the battery power employed, the coil gave continuous sparks about 4 cm. in length between its own terminals.

Increased sensitiveness was obtained by weighting the mirror so that its centre of gravity was behind, and slightly above the points of suspension, after which the tension was adjusted so that, when vertical, it was near a position of unstable equilibrium. A deflection of at least 10 divisions was then obtained with the oscillator at a distance of 4 metres; but the difficulty of using the instrument was greatly increased, since a small change of temperature, such as might arise from a slight draught, would alter the zero point very perceptibly. Theoretically, wires of some other material, *e.g.*, copper or aluminium, should give better results; but in the experiments made, the results obtained with them were less than before. Since everything depends on the tension in the wire being of exactly the right amount, the deflections might, however, the author thinks, be increased by employing very fine wires of copper or aluminium. The author considers that the possibility of compensating the platinum wire by means of a glass tube is an important point in favour of the method.

DISCUSSION.

In the discussion which followed,

Prof. PERRY inquired what would be the steady E.M.F. which, if it acted on the screw wire, would produce a similar effect. He suggested that copper ought to give better results than platinum, since, for a given E.M.F., the heating effect would be so much greater. He also suggested the use of a twisted strip, with a double twist, formed by taking a 2-mil copper wire, flattening it as much as possible, and then, after fixing it at the centre, twisting the ends about the axis of the strip, passing the fingers along the strip so as to have a uniform twist throughout the entire length. About one turn to an inch would be sufficient.

Mr. BOYS suggested that it was possible, though not very likely, that the elongation might be a direct effect of the current and not due to a rise of temperature, and he suggested that the point would be worth clearing up.

Prof. S. P. THOMPSON, with regard to this observation, asserted that Edmund's experiments had shown that there was no galvanic expansion in a wire traversed by an electric current, except that due to the heating effect.

Mr. GREGORY, in reply, said that he had made some tentative experiments with continuous E.M.F.s, but up to the present he had not obtained any very definite results. He had tried copper wire, but assuming the currents to be uniformly distributed through the thickness of the wire, aluminium ought to give results ten times as good.

Mr. GREGORY then read a Paper

"On a Method of Driving Tuning-Forks Electrically."

The author pointed out that in the ordinary method of driving tuning-forks by electricity, the battery circuit is completed just before the end of the stroke, and broken again soon after the commencement of the return motion, so that the fork receives the impulse at the most unfavourable moment, viz., when stationary. The impulse can be delayed to a considerable extent by including a solenoid in the battery circuit, and inserting into the solenoid an iron core, the distance to which it is inserted being determined by trial, so as to give the best effect. The driving, however, does not remain uniform. In the method devised by the author, the fork receives the impulse at the most favourable moment, viz., when it is moving with its greatest velocity.

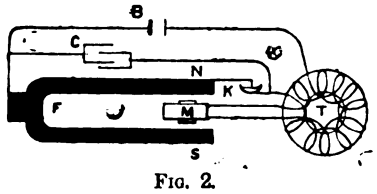

FIG. 2.

A tuning-fork, E (Fig. 2), mounted in the ordinary manner, is provided with the usual driving magnet, M, and mercury contact, K; but instead of taking the main battery current directly through the electro-magnet, M, it is sent through the primary coil of a kind of transformer, T, the secondary circuit of which is in connection with the electro-magnet, M.

The result of this arrangement is that the momentary induced currents, occurring both at making and breaking the main circuit, pass through the magnet alternately in opposite directions; and the fork being polarised, or converted into a horse-shoe magnet, the impulses are made to act as attractions and repulsions alternately, so that the fork receives two impulses instead of only one during each complete vibration. By properly adjusting the contact, so that it breaks the circuit at the moment when the fork is at rest, these impulses are given in the middle of the stroke.

The fork used in the author's experiments had prongs 20 cm. in length, and the distance between them was 1·8 cm. It made about 86 vibrations a second. The electro-magnet, M, was made by winding about 50 turns of No. 22 silk-covered copper wire round a core consisting of a bundle of varnished iron wires. It was mounted upon a wooden support maintained parallel to the prongs, and capable of sliding between them. The transformer, T, was composed of a core of cotton-covered iron bonnet wire, in the form of an anchor ring, with a mean diameter of about 6 cm., and a thickness of 1 cm. The secondary wire, consisting of about 160 turns of No. 22 silk-covered copper wire, was wound upon this, and the primary, consisting of about 190 turns of similar wire, was wound on over the secondary. In order to diminish sparking, a condenser of about 4 microfarads capacity was connected with the terminals of the mercury contact-breaker, K. A current of about 2 amperes, obtained from a small accumulator, B, was employed to work the apparatus. No attempt was made to use less battery power, but there can be no doubt that this could be done if the number of turns of wire were increased. There would probably, however, be a limit to this, as the lag would ultimately become so great as to interfere with the proper timing of the impulses.

The author then described an alternative method requiring far less battery power, but necessitating two contacts, as shown in Fig. 3.

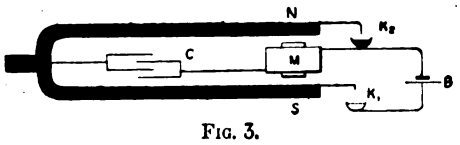

FIG. 3.

The condenser is charged through one contact, K_1, and discharged through the other, K_2. The currents, both charging and discharging, are taken through the electro-magnet, and the action is of the same kind as in the instrument previously described. The electro-magnet, M, must be wound with a large number of turns of fine wire, and a large condenser and powerful battery are required. The latter might, however, probably be replaced by a polarised battery of lead or platinum wires immersed in dilute sulphuric acid. Except with respect to economy of working, the second method is inferior to the former one, as the adjustment of the contacts, K_1 and K_2, would have to be made with great exactness. In case of objection being taken to the necessity of magnetising the fork, the author pointed out that forks driven electrically in the ordinary manner soon become magnetised; and, as a matter of fact, the fork first experimented with by the author had acquired its magnetism in this manner, and did not require any further magnetisation.

DISCUSSION.

In the discussion which followed the reading of the Paper,

Prof. S. P. THOMPSON observed that the device of introducing an induction coil was an extremely elegant one. If the method proved to be workable with a smaller current, the author would have supplied a great desideratum. In order to test the constancy of the vibration, he suggested the employment of a pair of forks of the same period, one of which could have a lens attached to one end, so as to determine the vibration period optically. He did not approve of a suggestion made by the author, that the phase of the E.M.F. might be retarded by the introduction of self-induction, for a contact taking place at the end of the throw would depend on the time occupied by the excursion. He did not believe that the author's second method would be a useful one, as, owing to mechanical drag, the contact would probably not occur exactly at the centre.

Prof. J. V. JONES suggested that the author's arrangement should be tested for constancy by taking simultaneous records from the fork and from a clock, a method which he himself had employed with success.

Mr. GREGORY, in reply, thanked Prof. Thompson for his suggestions, and maintained that the mercury cup contact could not be very far out as the fork was found to drive all right.

THE WESTERN AND BRAZILIAN CABLE COMPANY AND THE BRAZILIAN GOVERNMENT.

Mail advices from Rio, of October 7th, bring particulars of the refusal of the Government to permit the laying of a second cable along the coast from Rio de Janeiro to Pernambuco, once more illustrating the utter disregard of the Brazilian Government for commercial interests. The old cable having broken, the Western and Brazilian Company had a new cable made for the service, but the Government is represented to have refused to allow it to be put down because the Company had not submitted its contract with

Digitized by Google

the Brazilian Submarine Company for Government approval. The "Associacao Commercial" petitioned for the new cable to be laid in the interests of trade and commerce, but in vain. The *Rio News* states that during the long interruption between Rio and Bahia many merchants preferred to send their messages *viâ* Buenos Ayres, Valparaiso, and Galveston, rather than submit to the delays, annoyances, and extortions of the State telegraph service. The *News* argues that the licence to operate a cable implies the repair or substitution of the first line, or any improvement for the benefit of the service, otherwise the granting of a privilege for 90 years would be a farce. Our Rio contemporary hints that the real reason of the difficulty lies with subordinates whose object it is to divert the traffic on to the State lines. "For this reason," says the *Rio News*, "as well as for improved facilities in rapid telegraphic communication, we want another line along this coast which shall be under private control."

The fact is that after granting the concession to the Western Brazilian Telegraph Company, and permitting it to lay its cables, the Brazilian Government erected and worked competing land lines of their own down the coast, and gave as a reason for this hostility to that and the Brazilian Submarine lines the fact that the two Companies have a joint-purse agreement; although at the time this was concluded the Government were offered a liberal proportion of the joint revenue if they would bring the receipts from this land line into the arrangement. They, however, refused to do so, and as a measure of retaliation upon a Company with which they have entered into competition, notwithstanding that it works under their own concession, they simply obstruct progress.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *October* 26, 1889.

Overhead Wire Agitation in New York.—The question whether the wires shall go underground or shall stay overhead continues to be the leading one that agitates the New York papers and the mind of the New York public. As may be expected at such a time, any number of wild, irresponsible statements are being made by the press in their efforts to show how deadly a thing the electric wire may be, and the consequence is that the public is in a state of confusion worse confounded on the subject. Just what the outcome of the agitation will be nobody knows, and the local electric light companies, more particularly those engaged in lighting the streets, are in a state of desperation. At the present time there are no fewer than four official Boards indulging in a war dance over their unfortunate bodies, and each seems anxious to outdo the other in absurdity of propositions. What the Board of Electrical Control can do we are pretty well aware of by this time. This distinguished Board, which consists of a theatrical manager, a law clerk, and a retail butcher, has done its best to muddle and complicate the situation, and has frustrated well-nigh every effort that its energetic expert, Dr. Wheeler, has made to get things straightened out and in good shape. It is openly alleged that the Board is in close alliance with the Subway Company that has the contract for undergrounding the wires. Then the Department of Public Works has taken a hand in the matter, and by its activity in getting down the poles and wires has threatened to usurp the functions of the Board of Electrical Control, whose very supineness has been one of its saving recommendations as far as electricians are concerned. Next we have the Board of Health, which has been attempting to enforce some regulations insisting that continuous currents above 700 volts, and alternating currents above 250 volts, shall be prohibited. One of the evening papers distinguished itself by calling on this Board in a frantic manner to do something. Something was done, but the Corporation Counsel informed the Board that it had no authority in the matter; whereupon it and its enthusiastic coacher of the press incontinently subsided. The next body to take up the matter is the New York Board of Alderman, who now propose to conduct an investigation into the subject of overhead wires, and are already preparing to do so. Where a choice comes as to which of these bodies they would rather deal with, the local lighting companies feel that they are between the Devil and the deep sea, and their choice, if they have any choice left them, is only likely to add to their embarrassment and alarm. If there were any decent system of subways in existence, the companies would probably be more willing than they are now to go into them; but these subways are not satisfactory. The rate charged for a duct is no less than $800 a mile. The manholes are conspicuously small and inconvenient. The whole system keeps on filling up with gas and water, and explosions at the manholes are events of regular occurrence. It is the constant fear of being driven at any moment, such as the present, into these subways that has kept the local companies from putting their circuits into decent condition. As everybody knows, some of the old circuits are in extremely bad shape, as far as insulation is concerned, while the pole lines present a very ragged appearance. Since the accident to the lineman Feeks, nearly all the arc-lighting circuits on the streets have been shut down, and New York every night has been enveloped in a Stygian gloom. The streets have presented a most woeful appearance; the sandbagger has been on the alert, and robberies and assaults have been frequent. Yet the public have submitted to this, under the impression that it was necessary, and in some cases the panic has gone so far that people have refused to allow bell-wires to be run through their houses, under the impression that the touch of a push-button would bring them to the favourable consideration of the coroner. The whole business, in fact, is a sorry mess, and it is difficult to tell just what will be the next turn in the affairs. Probably we shall see considerable work done on the subways; but it is to be hoped that the new ones will be better than the old. Possibly it may be determined to bury only telephone and telegraph wires and low-tension circuits in general, at the same time adopting a system of carrying the high-tension wires far overhead where no other rotten wires can possibly come in contact with them, and where they will practically be as remote from the public as though they were at the bottom of the Hudson River.

Meeting of the American Street Railway Association of Minneapolis.—After the contemplation of New York at this time, and realising what grave effects throughout the country any hasty action here is likely to have, it is a positive relief to turn from electric lighting and look at the magnificent work that is being done in the development of electric railways. At the eighth annual meeting of the American Street Railway Association held at Minneapolis, the time and attention of the delegates was generally occupied with the consideration of electricity as a motive power. The President referred to it, the Executive Committee touched on it, and the report of the Special Committee on the subject was a striking vindication of all the claims that have been made as to the superiority of electricity for this purpose. The President in his opening address quoted the observation of a negro down South, who when he saw the electric car for the first time exclaimed exuberantly, "White man freed de darkey first, and now he freed de mule!" The Executive Committee said that during the last few years each succeeding year had seen electricity progress far more rapidly than any other motive power that had come to their notice, and they observed that this had been especially so in the organisation and operation of new roads. They considered it to be the duty of the managers of street railways to do all in their power to substitute some motive agency for animal, the inference being, of course, that they favoured electricity, it being the only available substitute for the horse on the vast majority of lines in this country. The report of the Special Committee on electricity, signed by Mr. Thomas C. Barr, chairman, is one of the most encouraging documents of the kind that I have seen for a long while. Mr. Barr gives a large variety of figures to show how electricity compares with other methods of operation, and adds:—"If it is desired to make a change from horse cars, electricity will fill the bill to perfection, no matter how long or short the road, or how many passengers are carried. In the investigation of the subject the most satisfactory results had been shown, and it not only increased traffic over the roads but reduced expense, and it enabled us to operate a line, which heretofore entailed a loss, at a profit." Mr. Barr also included in his report the operating expenses, gross earnings, and nett earnings of several roads employing electricity, and in each case the most remarkable development of capacity and profits was

Digitized by Google

shown. Mr. Barr also cited the reports made at Boston, where it appears that on the electric extension to Arlington, on the Cambridge division, there has been an increase of 150 per cent. in traffic, with 50 per cent. decrease in the operating expense, giving a nett gain of 200 per cent. The discussion on this interesting report elicited further significant figures from gentlemen running electric roads, and the whole session was one of the most remarkable triumphs of electrical application that could possibly be imagined. The development has been rapid up to this point, and the rate of increase will certainly be even faster after such a meeting as that. The Convention of the Western Electric Railway Association was also held during the same week in Minneapolis, for the purpose of discussing questions pertaining exclusively to electric railway operations, and the work of this body naturally went to strengthen and confirm the favourable impression that electricity made on everybody present.

Annual Convention of the Railway Telegraph Superintendents at Washington, D. C.—The Railway Telegraph Superintendents held their annual Convention a few days ago at Washington, D. C. At one time it looked as though the work of these officials would be necessarily limited in its scope, but of late years, owing to the adoption of various electrical appliances for different parts of the work on the roads, the duties of the telegraph superintendent have tended to become more and more onerous. A significant evidence of this condition was given in the fact that one of the most interesting and important papers presented was that by Mr. Charles Selden, the well-known superintendent of telegraph of the Baltimore and Ohio Railroad, on the subject of "Train Electric Lighting." Mr. Selden has given considerable attention to this work in its various details, and brought the result of his observations before the Association in an elaborate and careful statement. Mr. Selden, with all his predilection for electricity, did not consider that, so far, under the methods adopted, electric lighting had proved to be all that was claimed for it, the main fault being that involved in a high rate of expense. The chief difficulty that Mr. Selden had was to get bottom bed-rock figures on the subject. Thus, for example, with the Pennsylvania Railway Company, which is very careful in such matters, he was only able to ascertain that the company had determined that its system of changing the batteries on each run of the train was a little more expensive than oil, but, at the same time, was cheaper than the gas that they used formerly from reservoirs placed under the cars. Mr. Selden said that the system of lighting direct from a dynamo upon a train without the auxiliary help of a storage battery is not in use, but he did not see why it would not be a good thing to do, and save the expense both in plant and the depreciation of the storage battery. There was, of course, the objection that in case of any failure in connection—engines and dynamo—the lights would go out, leaving the train in darkness. This, he thought, however, could be obviated by keeping one candle and one lamp in each car, it being necessary to carry lamps and candles anyhow for emergencies. Mr. Selden gave, in addition, a very careful account of the method adopted by the Pullman Company, which runs a plant on board its vestibule trains, comprising an engine, a dynamo, and storage batteries, so that there is no need to remove the cells at any time; and hence, it is claimed, a longer life for them is secured. The expense of operating such a plant might be lessened, he thought, by placing it in charge of the baggage master, as he certainly ought to be able to attend to it. Some of his colleagues did not agree with him in this respect.

Electricity in Relation to the Human Body.—*Scribner's Magazine* will add next month to its interesting series of electrical articles one by Dr. Allen Starr, on "Electricity in Relation to the Human Body," in which the line is drawn very sharply between the legitimate use of electricity and the quackery which has undoubtedly built up not a few large fortunes at the expense of the public health. Dr. Starr states that he once demanded of the agent of a widely-advertised electrical belt some proof that an electrical current was produced by it, and he suggested that any such current could be detected by means of a galvanometer. This test was objected to; but a little frame, holding a dozen pocket compasses, was produced, and the power of the belt, which, doubtless, contained some iron plates to attract the needles of these compasses, was shown as truth of the assertion that the belt was a powerful generator of electricity. Probably many of those before whom this test was made were not able to distinguish between electricity and magnetism, and quietly gave up their ducats to the charlatan with whom they were dealing.

CORRESPONDENCE.

CONTINENTAL AND ENGLISH GENERATING PLANT.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In Mr. Snell's interesting Paper on the dynamos at Paris, mention is made of the use in England of a frame-shaped bed, with the pole-pieces (of machines having the Edison type of field) sunk into the centre hollow, in which they are suspended by brass brackets. Machines of this type are stated to have been built by Messrs. L. Clark, Muirhead, and Co.; by Messrs. Crompton and Co., and by Messrs. Siemens and Co.; and in a footnote you instance the machines at Bradford and at Kensington Court as being of the description named. Mr. Snell also speaks of the system as "chiefly used for central-station work."

Perhaps you will allow us to point out that the construction referred to is that due to the use of Willans' Patent Combination Frame for engines and dynamos, and that not only the firms named but others are accustomed to make this type of machine for direct coupling to the Willans engine. It may also interest you to know that, besides the machines at Bradford and at Kensington Court, dynamos of this type (of course coupled direct to Mr. Willans' engines) are in use at, or are on order for, the following installations—viz., Liverpool, about 1,500 horse-power; Pall Mall (Mason's Yard), 2,200 horse-power; Gatti's Restaurant, &c. (with Edison-Hopkinson machines), about 550 horse-power; Savoy Theatre and Hotel, 650 horse-power; Whitehall Court station, 600 horse-power; Mr. D'Oyly Carte's new theatre, 400 horse-power; Leeds Fine Art Galleries, 300 horse-power; Post Office buildings, London (Elwell-Parker dynamos), 400 horse-power; and another installation in London (Goolden dynamos), 300 horse-power; while dynamos of the same pattern for minor installations on land have been coupled to Willans engines capable of developing over 3,000 horse-power, and for ship use to the extent of over 8,000 horse-power. It will therefore be seen that though the system is largely and increasingly adopted for central station work, it has been even more widely used in general installations, and on board ship. In central-station work the horse-power of Willans engines, coupled direct to dynamos mounted on bed-plates of the combination frame pattern, is, so far, less than that applied on bed-plates of other patterns. The balance is likely, however, to be on the other side before long.

The absence of this type of machine at Paris is probably due to the fact that, owing to our hands being so full of English work, and to the hindrance to business (now happily at an end) caused by the destruction of our works by fire last year, the Willans engine is little known as yet upon the Continent. The same reason may assist to explain the extremely low speeds of the large continental machines intended for direct-driving. They are simply made to suit engines which are incapable of running fast, and continental makers will see as clearly as English ones the advantage of using smaller machines and higher speeds, when they realise that an engine which is superior to their own elaborate and costly types in every respect of steam-economy, simplicity, cheapness, and durability, is also available for continuous running *at double speed*. For instance, the Willans central-valve engine of 200 horse-power (I. I. standard pattern, of which over fifty, coupled direct to dynamos, are now at work or under construction) has a standard speed of 375 revolutions—which is certainly double the speed at which any one would care to run a double-acting engine of like power; and even the engine of 550 horse-power (K. K. size) has a standard speed of 260 revolutions.

Digitized by Google

In any critique upon Continental electric generating plant as a whole, it appears to us that justice to the widely different system which obtains in England requires that attention should be directed to the enormous costliness of the foreign systems, both in space and in material—and doubtless in money. It is no exaggeration to say that any one of the electric generating buildings at Paris, with its enormous horizontal engines, and costly and noisy belts, and (in some cases) countershafting, might contain engines and dynamos on the English system, with an output at least five or six times as great (in some cases eight times as great), with a materially smaller steam consumption per electrical horse-power, and with probably little or no increase in the number of attendants or in the cost of maintenance. Unfortunately, the destruction of our works last winter prevented us from making any show of direct-driving engines at Paris, or the two systems might have been seen side by side.

Mr. Snell's remarks upon the unequal magnetic pull upon the armatures of single-limb-magnet two-pole machines are much to the point, and it is probable that in really large two-pole machines with the yoke below, the difficulties of working will be found very great, through the excessive pressure on the shaft and bearings, due to gravity and the magnetic pull combined. In large machines of the inverted horse-shoe pattern the pull does not produce merely a diminution in the weight of the armature on the bearings—it frequently overcomes it, so that the armature shaft revolves solely against the cap of the bearing; but by suitably boring the pole-pieces (not merely placing the armature out of centre) the pull can be lessened until it just fails to balance the weight, when the armature will, of course, run in its bearings almost without friction. Thus the difficulty which Mr. Snell refers to becomes an advantage. (It may be well to say that our experience is chiefly with machines having drum armatures).

We enclose a section of the Willans' combination frame applied to a dynamo absorbing rather over 200 indicated horse-power; the other end of the frame forms the lower part of the engine crank chamber. The width over all is about 4ft. 8in.; length of engine and dynamo, over all, not quite 14ft.; weight of engine, dynamo, and bedplate about 12¾ tons.—Yours, &c.,

For Willans and Robinson (Limited),
H. Farmer, Secretary.

Ferry Works, Thames Ditton, Surrey,

THE USE OF STEEL BEARERS FOR OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: I see by the paragraph relating to overhead wires, in your report of the meeting of the Electrical Trades Section of the London Chamber of Commerce, that the Council of the Institution of Electrical Engineers decided at present not to recommend any alteration of the Board of Trade rule referring to the use of steel bearer wires to carry the weight of copper leads.

As a practical electrical engineer, I should have thought that, although the use of bearers might be a necessity is cases of the long spans so usual in over-roof work, surely the disadvantages of increased strain to standards and additional resistance to wind pressure would not be so sufficiently compensated for by increased safety as to sanction their use in the case of very short spans.

In provincial towns where the electric light leads are supported on standards from 40 to 50 yards apart, I think, with due deference to the opinion of our learned Council, that the use of bearers is likely to be a questionable advantage.

I am glad to find that the Board of Trade are considering the plan of using silicium or other bronze wires.—Yours, &c.,

Practical Electrical Engineer.

November 6, 1889.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Some time ago I drew attention in your columns to the curious devolution which has taken place in the history of the society now known as "The Institution of Electrical Engineers." It began as the "Society of Telegraph Engineers," and in process of time, when it was full-blown and prosperous, it permitted the adoption of an outside branch of the same science, "the Electricians." In process of time the adopted bantling, like the growing cuckoo in the hedge-sparrow's nest, began to assert itself, demanding and obtaining due recognition, the society becoming "The Society of Telegraph Engineers and Electricians." In the great impetus given to electricity by the invention of the telephone and the development of the electric light, the bantling began to oust the parent-birds and their legitimate offspring, until to-day, to drop the simile, under a changed name, and with a management from which telegraphy (*qua* telegraphy) has been eliminated, the "Institution of Electrical Engineers" stands confessed as the society of all the branches of electricity—except telegraphy—for Mr. Preece and Mr. Graves are on the Council not in virtue of their telegraphic eminence, but because they are the representatives of the Government, and eminent in other branches of the science. Besides, it is no secret that they have withdrawn much of their active support from the Council under the new *régime*. To any one who knows the tone of a large majority of the Council towards our branch of the profession, and the contempt with which they speak of it as unworthy the attention of "scientists," this is not to be wondered at.

With such a history and such a tendency it was surely a cruel fate which made the first dinner of the reorganised society on Monday night the medium for the splendid eulogy of Submarine Telegraphy from the lips of the Prime Minister. Indeed, all the other speakers were compelled to follow Lord Salisbury's lead and add their tribute to the glorification of the despised branch which is not considered good enough to be represented on the Council. The noble Marquis might have stared himself blind before finding a single representative of the great Cable Corporations whose services to Britain and to the world he was celebrating, for the solitary cable magnate present, Sir James Anderson, was, in accordance with the policy of the Council, relegated to an obscure corner. Where were Sir John Pender, Lord Monck, the Marquis of Tweeddale, Henry Weaver, William Andrews, Sir Geo. Elliot, and other founders and directors of ocean telegraphy, who, by their enterprise, perseverance, capital, and untiring energy, have connected England with her Colonies and dependencies and with the other nations of the world? The Anglo-American, Direct United States, and the other Atlantic cables; the Eastern, Eastern Extension, and other lines connecting England with China, Japan, Australasia, India, and South Africa; the South American cables, and all the others whose 35 millions of capital and 120,000 miles of cable lie at the bottom of the sea were conspicuous in a very literal sense by the absence of any invited representative; there was only one gentleman there who could appropriate any share of Lord Salisbury's eulogy, or return thanks for his appreciation of the services rendered to successive Governments, and it does not appear that he was asked to do so.

Should anyone suggest that this remarkable absence was due to accident, and not to design, let him examine the list of Council, and say if there is a single manager or representative of cable telegraphy thereon. It may also be suggested that this argues a decline in telegraphy itself, but a careful study of the list of members and associates will show large numbers of telegraph, railway, and cable men. These (especially the cable men) are for the most part far from London, and having neither voice nor vote in the management of the society, have been unable to prevent the overthrow of their *confrères*. From the dissatisfaction which is felt at the course of events in the present society, I am convinced that the time has come when the telegraph men should withdraw and make a fresh start with a new Society of Telegraph Engineers, and from the Post Office, the railways, the manufacturing firms, the telephone and the cable companies a sufficient membership can be certainly counted upon to give the new venture an excellent start.—Yours, &c.,

THE EMPLOYMENT OF CHROMIC ACID INSTEAD OF NITRIC ACID IN THE BUNSEN CELL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I venture to express my surprise that Mr. J. Wilson Swan should say that but small success has attended the endeavour to escape the necessity of employing nitric acid in battery cells, and that it was impossible to get the effect required without some nitric acid. Mr. Swan further adds that where a large current was required to be steadily maintained for several hours, the substitution of chromic for nitric acid proved to be wholly inefficient.

This is not my experience as a practical user for several years of chromic acid batteries. With the introduction of chromic acid, as made by Mr. Rowell's process, my batteries will run very constant for thirty or forty hours, giving a strong current. This has been fully proved by Mr. Rowell, who has tested them. I use no nitric acid in the cells. I am acquainted with the Holmes-Burke construction and the formula for charging; but I cannot see that Mr. Swan's plan of swaddling them up in sawdust, like a Norwegian kitchen, would tend to lessen the internal resistance of the cells, or improve them. At least, I do not see the advantage of it.—Yours, &c.,

November 5, 1889. CHARLES PENRUDDOCKE.

OCEAN CABLE REPAIRS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read in your issue of 1st instant an article on ocean cable repairs, extracted from the *New York World*, and think it right to correct some of the principal inaccuracies.

The writer states that icebergs pick up the loops of cable suspended between two submarine mountains, and carry them onward until the strain results in an absolute rupture. I have to state that there is no evidence of anything of the kind having ever happened.

Then the article speaks of one cable having been broken by a whale as a Munchausen story, and of another having been injured by a swordfish as a fairy tale; but I can say positively that both circumstances have occurred, only read *sawfish* instead of *swordfish*.

The account of picking up cables is, perhaps, sufficiently graphic and interesting for the general reader. I only wish, however, it was so easy to repair them as to be certain of accomplishing the work within three weeks, which is said by the writer to be the average time.

The extract also states that "Presumably the cost of laying a carpet bears the same relation to the cost of the cable as the *cost of carpet-laying does to the price paid for the carpet.*" This, if it were so, would indeed be satisfactory to cable companies; but, unfortunately, it does not in any way represent the facts of the case.

The last paragraph of the article is altogether misleading. I am sure the "Faraday" never attempted to pick up any of the cables laid by the "Great Eastern." Then it is stated that "the only thing the searchers (on the 'Faraday') had to guide them in their search was the log of the steamship 'Great Eastern,' which made known the course of the vessel certainly, but not with the extreme accuracy which was in such a case desirable." I may be allowed to state that the "Great Eastern," having lost the 1865 cable, steamed in 1866 direct to the spot where the cable was lost and recovered it, also that every mile of the "Great Eastern's" track on all her cable voyages was laid down with such accuracy as left nothing to be desired.

The whole of this paragraph is so very wide of the mark, not to say absurd, that it is evident the writer has never read the story of Atlantic telegraphy.—Yours, &c.,

JAMES ANDERSON.

Winchester House, 50, Old Broad-street,
London, E.C., November 4, 1889.

OVERHEAD WIRE RULES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The following is an extract from a letter from Major Cardew:—"I see there is a mistake in the report of the Chamber of Commerce. 'Low Pressure' has not been altered to 600 volts. But when the total potential difference cannot exceed 600 volts, and where the circuit can be earthed in the middle, and where the potential difference between any wires on the same poles or supports cannot exceed 300 volts, the wires are 'low pressure.'

"Instances:—A 5-wire battery system, 110 between each pair of wires, or a 10-arc circuit with a return wire led back by a different route."—Yours, &c., ALEX. P. TROTTER,

Correspondent of the Section.

LEGAL INTELLIGENCE.

An Injunction.

Mr. E. Ford on Thuraday last week applied to Mr. Justice Chitty, in the Chancery Division, on behalf of Mr. Monteith, of Leeds, for an interim injunction, with leave to serve notice of motion with copy of the writ in the action on the liquidator of an electric lighting company, to restrain him from removing from the plaintiff's premises the apparatus for lighting those premises with electricity. The circumstances under which the application was made were that in October, 1888, the company entered into a contract with Mr. Monteith to light his premises electrically for five years. The company since then had gone into liquidation, and a liquidator had been appointed. This gentleman, it was said, finding the contract an unprofitable one, had determined not to continue it, and he had given notice of his intention to remove the plant. The premises, not having sufficient gas-lighting power, it was alleged would be left in darkness if the electric lighting was discontinued, and on the ground that the contract of the company ought to be carried out, the plaintiff sought the relief of the Court, and Mr. Justice Chitty granted it.

United Telephone Company v. Smith.

This case came before Mr. Justice Chitty, in the High Court of Justice, on Saturday last, on motion for judgment in default of pleading by the defendant. The action was brought by the plaintiffs to restrain the infringement by the defendant of two of their patents. Counsel now asked for an injunction for delivering up of the instruments, an inquiry as to damages, and an order to pay the amount of such damages. The plaintiffs also asked for their full costs, charges and expenses, as between solicitor and client, up to and including the judgment, with liberty to apply as to future costs in chambers.

His Lordship made the order.

COMPANIES' MEETINGS & REPORTS.

Brazilian Submarine Telegraph Company (Limited).

The thirty-second ordinary general meeting of the shareholders of this Company was held at Winchester House, Old Broad-street, on Wednesday last. Sir James Anderson, in the absence of Viscount Monck, the Chairman, who was unable through indisposition to be present, presided.

The SECRETARY (Mr. Richard Collett) read the notice convening the meeting and the minutes of the last meeting, which were approved by the present meeting, and signed by the Chairman as correctly entered.

The report of the Directors was taken as read.

The CHAIRMAN said that the report presented, as usual, some of the phases incidental to telegraph companies. There had been ups and downs in the period under review. It would be found that they had lost £20,000 in their receipts compared with those of the previous half-year, though they had made nearly £4,000 more than they did in the corresponding period of the previous twelve months. That great reduction in their revenue was due mainly to interruptions in the Western and Brazilian line. He supposed they had seen by the newspapers the number of interruptions which that company had experienced, notwithstanding that they had left no stone unturned to get leave to duplicate their lines, and had had as many as three steamers on the spot for several months to effect repairs. He was glad to say that at present all the cables were working and their revenue was very good. Whether their friends would be allowed to duplicate their cable or not seemed to be a knotty question, but they said that they were using every endeavour to bring that about, and if the Brazilian Submarine Telegraph Company could possibly assist them in their efforts in that direction they would do so. At present there was some strong obstruction in Brazil which had not been overcome. That was the black side of the shield. The opposite side showed that the Company had a growing traffic and had £75,000 invested in the African Direct Line. Cables had been extended down to the Cape of Good Hope, and this Company had a joint-purse arrangement with those companies working down to that Coast, including the Eastern and South African Company. The revenue accrued in the current half-year from that source was £3,300, and Mr. Fuller, the Managing Director, estimated that the revenue that would accrue for the current 12 months from that cable, and from their proportion carried from St. Vincent to Lisbon, would be £14,000. So there were two sources of income, making up for some of those circumstances which adversely affected their earning power. He could congratulate them on receiving a very good dividend—the best that had ever been paid by the Company—while they would also find that they had a diminishing deben-

Digitized by Google

ture debt and a growing reserve. He would just like to say in this connection and "off his own bat," as it were—for it was his strong opinion—that there was nothing he liked better to see than a diminishing debt and a growing reserve. He thought that any one having an intimate knowledge of the effect of age, accidents, and possible opposition at all times, and the determination of different foreign Administrations, who had nothing to lose, to force companies down to lower tariffs, would be glad to see their reserve largely increasing. If he had his own way—that was to say, if the property were entirely his—he ventured to say that he would not credit himself with more than a 6 per cent. dividend at the very outside until he saw the reserve exceeding half a million and the debenture debt paid off. If any of the proprietors would be good enough to urge the adoption of that policy on the Board he thought they would take it into consideration very seriously at the next meeting. It was a matter for the shareholders, however, to determine. He concluded by moving the following resolution:

"*That the report of the Directors and the accounts to June 30, 1889, now submitted be approved and adopted, and that a dividend be now declared of 1s. per share (making, with the interim dividends already paid, a total dividend of 6 per cent. for the year ended June 30, 1889), and also a bonus of 3s. per share, in respect of the profits for the year ended June 30, 1889, the said dividend and bonus to be respectively free of income-tax.*"

The Hon. W. ST. JOHN F. BRODRICK, M.P., seconded the motion.

Mr. THEODORE CARTER was sure that the shareholders must agree with the Chairman, that the best thing they could do was to increase their reserve and diminish their debenture debt. There had been rumours of a fresh cable being laid to the River Plate. Might he ask whether there was any truth in those rumours, and in what way would an opposition cable, if laid, interfere with the present traffic of the Company?

The CHAIRMAN, in reply, said the Directors knew only what the shareholders themselves knew from what they read in the newspapers regarding a new cable. He did not know what its effect would be if laid. But if foreign Governments would continue to give subsidies to opposing companies it only remained for the Company to meet such opposition manfully. He was not sure that it would come about, but, at the same time, he was not aware of any means of preventing it if the Argentine Government thought proper to give a guarantee. The matter, however, had not come before them in a tangible shape so that they might grapple with it. But, as he held out to them in his remarks, they must look forward to things of that kind. There were always men of enterprise to be found, and if those men got foreign Governments to give them subsidies, the telegraph companies must be prepared for such contingencies. But he did not despair even if an opposition cable were laid, for they should even then be a dividend-paying Company. He did, however, like the policy of keeping the capital down as far as possible so as to pay a moderate dividend in adverse times, and of having a large reserve in order to keep the shares before the public as a valuable security, and he thought they were maintaining that position satisfactorily.

The resolution was unanimously adopted.

The CHAIRMAN next moved—

"*That the Right Honourable Viscount Monck, who now retires by rotation, be and is hereby re-elected a Director of the Company.*"

Sir HENRY D. GOOCH, Bart., seconded the motion, which was carried unanimously.

The CHAIRMAN next moved—

"*That the Duke de Loulé, who now retires by rotation, be and is hereby re-elected a Director of the Company.*"

Mr. THOMAS FULLER seconded the motion, which was also agreed to *nem. con.*

Mr. I. ANDERSON afterwards proposed—

"*That Mr. Henry Dever and Mr. John Gane be and they are hereby re-elected auditors to the Company for the ensuing year, with the remuneration of £50 each.*"

Mr. W. GRIFFITH seconded the motion, bearing warm testimony to the ability of the officers of the Company, and to the efficiency of the audit.

The resolution was cordially agreed to.

On the motion of Mr. GRIFFITH, seconded by Capt. BLAKEY, R.N., a cordial vote of thanks was passed to the Chairman and Directors.

The CHAIRMAN briefly acknowledged the vote, assuring the shareholders that their business had the constant and anxious care of the Board. The oppositions, to which reference had been made, did not spring up without giving the Directors occasion for much thought and frequent consultation. All that they could promise to do was to act steadily, daily, and always in the best interests of the shareholders.

The proceedings then terminated.

The Western and Brazilian Telegraph Company (Limited).

The following is the report of the Directors to be presented at the eighteenth ordinary general meeting, to be held at Winchester House, E.C., on Wednesday, the 13th inst., at 12 o'clock:—

The total earnings amount to £86,555. 17s. 10d., as against £86,874. 7s. 11d.—a decrease of £318. 10s. 1d. compared with the half-year to June 30, 1888.

The working expenses amount to £39,104. 15s. 5d., as against £32,813. 7s. 10d.—an increase of £6,291. 7s. 7d.

The increase is attributable to the higher exchange and to the purchase of extra instruments and appliances, also to additional staff and their travelling expenses, necessitated by the prevalence of yellow fever on the coast, and by increased traffic. The Board have much pleasure in stating that the conduct of the staff under trying circumstances was beyond praise. The ss. "Buccaneer" was chartered to take the place of the ss. "Norseman," which was ordered home for new boilers and repairs. The amount of cable used was also larger than usual during this half-year.

Including the amount brought forward from 1888 (£3,461. 17s. 3d.) and the dividend received upon the shares held in the "Platino" Company to June 30th, the balance to the credit of the revenue account is £58,237. 19s. 8d., from which has to be deducted £13,500 for debenture interest, leaving £44,737. 19s. 8d., of which £7,500 has been placed to the renewal fund, and £5,600 to the debenture redemption fund. This leaves £31,637. 19s. 8d. The Directors recommend the payment of a dividend on the ordinary shares for the half-year at the rate of £4 per cent. per annum (6s. per share), carrying forward £4,072. 9s. 8d. At the corresponding period last year the dividend was at the same rate.

Since the last half-year's report 545 "Platino" shares have been exchanged for 327 shares of this Company.

The dividend will be paid on November 15th.

The report also contains some interesting information in reference to communications which have been exchanged between the Company and the Government of Brazil relative to the proposed laying of loop or alternative cables.

The West India and Panama Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ended June 30th last, to be submitted to the twenty-fifth ordinary general meeting to be held at Winchester House, 50, Old Broad-street, E.C., on Wednesday, the 13th inst., at 2 p.m.:—

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

1. The amount to credit of revenue is £49,985. 11s. 9d., and the expenses have been £24,458. 6s. 9d., leaving a balance of £25,527. 5s., which, with the balance of £1,154. 3s. 1d. brought from last account, makes a total of £26,681. 8s. 1d. Of this sum the Directors have placed £2,000 to reserve, leaving an available balance of £24,681. 8s. 1d., with which it is proposed to deal as follows :—

First Preference Shares—			
Balance of arrears of dividend, 6s. per share	£10,368	18	0
Dividend, six months to June 30th, 6s. per share..	10,368	18	0
Second Preference Shares—			
On account of arrears of dividend to June 30th, 10s. per share	2,334	10	0
Balance to current half-year's account	1,609	2	1
	£24,681	8	1

2. The traffic receipts for the six months show an increase of £672. 12s. 11d., as compared with the corresponding period.

3. The expenses for repairs to cables are £3,459. 9s. 7d. less than those for the corresponding half-year, owing to fewer interruptions. The Company's system is in good working order throughout.

4. The Company's ss. "Duchess of Marlborough" arrived in the Thames in May last, after an absence of four years; and having been surveyed and repaired, in accordance with Lloyd's requirements, returned to the West Indies with a supply of new cable for stock.

The Swan United Electric Light Company (Limited).

The following is the seventh annual report of the Directors of this Company, to be presented at the ordinary general meeting, to be held at the Cannon-street Hotel, London, E.C., on Thursday, the 14th inst., at two p.m. :—

1. The accounts accompanying the report are for the year ended September 30, 1889.

2. After paying all current charges, and making ample allowance for depreciation of plant, there is a credit balance of £21,042. 8s. 1d., to which must be added the credit balance of £10,052. 8s. 11d. brought forward from the last accounts, making a total of £31,094. 17s. The Directors will recommend the shareholders to declare a dividend of 6 per cent., which will absorb £22,208. 0s. 9d., to be distributed to the shareholders in accordance with Clause 77 of the Articles of Association.

3. The litigation in Germany still drags on, and, until some conclusion is arrived at, it is difficult to foresee whether a sound and remunerative business can be carried on in that country. The shareholders are aware that Germany is the only country on the Continent of Europe in which the Company now manufactures and sells lamps.

4. The Compagnie Générale des Lampes Incandescentes have established a new factory in Paris, which was brought into work last July, in which lamps are now being manufactured on a considerable scale. During the first six months of its existence, the Company worked under considerable disadvantages, having had to purchase the lamps required for their business, so that a small dividend only was earned, but there is every reason to hope that they will develop an increasing and profitable trade.

5. The Directors who retire by rotation are Mr. J. S. Forbes and Mr. E. W. Batt, who, being eligible, will offer themselves for re-election.

6. Messrs. Welton, Jones, and Co., the Auditors, will also retire, and will offer themselves for re-election.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended November 1st amounted to £4,506.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of October, 1889, were £2,900, as compared with £3,316 in the corresponding month of last year. The receipts for the month of July, estimated at £3,000, realised £3,003.

DIRECT SPANISH TELEGRAPH COMPANY.—The receipts of this Company for the month of October amounted to £2,625, against £2,210 for the corresponding period of last year.

EASTERN TELEGRAPH COMPANY.—This Company's traffic receipts for the month of October amounted to £62,981, and to £55,742 in the corresponding period of 1888.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this company for the month of October, 1889, amounted to £45,679, and to £38,660 in the corresponding period of 1888, an increase of £7,019.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—Notice is given, that on Friday the 15th inst, at noon, at the Company's offices, Winchester House, 50, Old Broad-street, E.C., 283 First Mortgage Debentures of £100 each will be drawn for payment on January 1, 1890. Notice will be given by advertisement of the numbers of the Debentures drawn.

ELECTRIC CONSTRUCTION COMPANY.—Application has been made to the Committee of the Stock Exchange for a special settling day in the shares of this Company.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of October amounted to £26,000. From January 1st to October 31st they were £229,200, against, in the corresponding months of 1888 and 1887, £226,200 and £220,880 respectively.

HALIFAX MUTUAL ELECTRIC LIGHT AND POWER COMPANY.—This Company, which is registered with a capital of £20,000 in 4,000 shares of £5 each, propose a first issue of 2,000 shares, payable 10s. per share on application, £1 per share on allotment, and the balance as may be required; purchase of the electric plant of Messrs. Blakey, Emmott, and Co. (Limited), and the Schmidt-Douglas Electric Company (Limited), at Halifax, and Amalgamated Halifax Supply.

SOUTH OF ENGLAND TELEPHONE COMPANY.—A half-yearly dividend on the Preference Shares, at the rate of 6 per cent. per annum, is announced by the Directors of this Company.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended October 31st amounted to £7,725.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended October 31st were £2,717, against £2,767 for the corresponding period last year.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 1st, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,112.

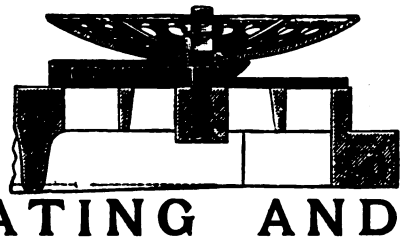
WOODHOUSE AND RAWSON UNITED (LIMITED).—The Directors announce a second issue of 10,000 ordinary shares of £5 each, 10,000 Preference of £5 each, at a premium of 5s. per share, and 400 Debentures of £100 each, at a premium of £2, being the balance of the capital of the Company. The prospectus announcing the formation of this Company was issued in July last, and it is stated that the wisdom of the amalgamation is shown by the fact that already more business of a profitable character has been offered than the capital issued enables the Company to entertain. The premiums received from the present issue will be carried to a reserve fund. The list closed yesterday for town, and this (Friday) morning for the country.

BUSINESS CHANGES.—Chutter and Gilbert, of Buckingham-street, Birmingham, electrical engineers, having dissolved partnership (Mr. Ralph B. Gilbert retiring), the business will be carried on in future by Mr. G. F. Chutter alone.

CHANGE OF ADDRESS.—Mr. Charles H. Yeaman informs us that his address is now 130, Bedford-street, Abercromby-square, Liverpool, and that he has removed from his London premises, 211, Isledon-road, Holloway, N.

PERSONAL.—Mr. Ernest Payne informs us that he has started business as an electrical and mechanical engineer, in conjunction with Mr. Carrington Smythe, at 140, Bath-street, Glasgow.

NEW VALVE



No Rubber, Percha, or Leather.

One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept., 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 600.—Vol. XXIV. FRIDAY, NOVEMBER 15, 1889. Price Fourpence.

NOTES.

The secretary of the Edinburgh Electrical Exhibition has been informed that the Institution of Electrical Engineers has decided to hold a special meeting in Edinburgh before or after the meeting of the British Association at Leeds. This arrangement, if carried out, will have the advantage of securing the presence of some at least of the leading members of the Institution at the Exhibition, and if a programme is carefully prepared, the visit should prove a useful one. We are a little inclined to question whether attendance at Section G will not have somewhat exhausted the capacity of peripatetic electricians to receive and contribute information, but the occasion might be improved by discussing in conference matters of more special interest to electrical engineers.

The little difference of opinion between the electrical trade and the Edinburgh Exhibition authorities may be now considered to be in a fair way to an amicable adjustment. The report of the special committee of the Electrical Section was brief and to the point, and the Exhibition authorities, speaking through their general manager, Mr. Lee Bapty, seemed disposed to meet the wishes of the trade more than half-way. The request for free space was met by the proposal, that after all legal demands had been satisfied, any balance that might remain in the hands of the Exhibition authorities should be devoted to reimbursing electrical exhibitors. Mr. Lee Bapty was also able to say that there would be no difficulty about supplying current free of charge to any exhibit which required it in order to be properly shown, while he was prepared to advise his Council to undertake the insurance of the exhibits. In short, the Exhibition authorities displayed a laudable spirit of concession, and we have every confidence that any outstanding point will be settled in an equally businesslike manner.

We note with satisfaction the proposal made by the Special Committee that there should be no awards; or, at any rate, that if there are to be awards, steps should be taken to improve upon the present ridiculous system of granting medals wholesale after what at the best can only be a cursory inspection of the exhibits. In our issue of July 26th we hazarded the suggestion that Exhibition Committees might draw up certain conditions to be fulfilled by different apparatus, and should award certificates to such apparatus as came up to the required standard. A certificate of this nature, if the conditions were stringent and the tests carried out by competent persons, would carry considerable weight, and would possess the decided advantage of doing away with the invidiousness of competition. We are glad to see that there is every probability of some such system being adopted at Edinburgh.

Among the many useful proposals which were made at the meeting of the Electrical Section of the London Chamber of Commerce on Monday last was the one due to Mr. Albright, that the Electrical Section should act as Commissioners for the electrical trade at the Edinburgh Exhibition. This suggestion was embodied in a resolution which was carried, and will therefore take a practical shape without delay. The arrangement is one which will considerably diminish the labours of individual exhibitors, and if, in addition, it ensures punctuality in the sending in of exhibits, it will deserve well of the trade and of the public. Perhaps one of the best results of Monday's meeting is the convincing manner in which it will bring home to the electrical trade generally the potential possibilities of united action, whether for defence or offence.

Our esteemed contemporary the *Electrical World* devotes an article to describing the methods suggested by M. Nikola Tesla for rectifying alternating currents. We must confess to a certain amount of scepticism as to the availability of these methods for large currents. On another page of the same journal M. A. Gaillard describes an apparatus for effecting the same purpose, which has a close resemblance to a device described by Mr. Lane Fox some years ago intended to do this. It is obvious, however, that anything like mercury cups or spring contacts, however effective for currents of a few amperes in magnitude, will fail when larger currents are used. The commutation of alternating currents by a motionless commutator capable of dealing with currents of all magnitudes and various frequencies is a problem which may well tax the highest inventive skill, but these devices of M. Tesla do not seem very perfect solutions of the question. The method adopted of splitting the alternating current through two coils having magnetically saturated cores is very ingenious, depending as it does on the fact that the self-induction of the coil varies with the permeability of the core, and this varies with the induction through the core.

The letter signed "Observer" which we print this week, criticising the one signed "Telegraphy" in our last, will, no doubt, provoke a suitable rejoinder. But with regard to that

Digitized by Google

portion of "Observer's" letter which relates to ourselves, we may say at once that in according "sympathy" to "Telegraphy" we did not, and do not, suppose that he wished for a "preponderance" of the telegraphic element in the society. In reality the alleged ground of complaint is, not that the founders of the Society have been taken at their word, but that after faithfully keeping it, they find themselves reduced to silence. We do not assert that this grievance has been deliberately inflicted; but knowing as we do that it exists, we wish to make it known and get it rectified.

When we are asked, "Do you consider electrical industry important?" we don't mind telling anybody that we do; but when the Chairman of the meeting of Operative Electricians founds on this answer the further question, "Then, why don't you think the operatives able to estimate the status of their occupation?" we are tempted to reply, "Because they elected a chairman capable of putting such a question." But in reality we have not denied their ability or their right to estimate their status as highly as they please, and the higher it is estimated the better we shall like it. What we do deny is that their status will be heightened by a semi-political and wholly aggressive combination against their employers. Our correspondent is as vague concerning the objects of the Union as was Mr. Rowlands, M.P.; and the only point on which definite information is vouchsafed is that "no incompetent workman will be eligible for membership." Of this law the writer assumes that there is nothing in it "detrimental to the interests of the employer." We are not so sure about that. The assumption includes the right of determining the competency of the workman—a function which employers can exercise, one would suppose, with quite as much judgment, and certainly with greater impartiality. In practical operation such laws are usually intended to be read backwards—that is to say, No man will be deemed competent who is not a member of the Union.

If litigation between rival patentees may be considered as an outward and visible sign that their patents are worth fighting about, it is probable that we shall shortly have this proof at least of the value of the process of electric tanning. Just twelve months ago (*The Electrician*, November 9, 1888), reference was made in our "Scandinavian Notes" to the fact that tanning by electricity had been successfully carried out at Nordköping, in Sweden. A few months later (*The Electrician*, April 19, 1889) we published a brief description of the Worms and Balé process, which had been tried with encouraging results in France. The Worms and Balé process is, we believe, now being worked in this country by the British Tannery Company (Limited), and the threatened litigation, which is alluded to above, is between this Company and Mr. L. A. Groth, the inventor of the Swedish process, which has been in experimental operation at Messrs. Tebbitt Brothers at Bermondsey.

MM. Worms and Balé, it will be remembered, place the raw hides inside a revolving drum containing ordinary tanning solution, *plus* a little turpentine, and pass a current through the drum; and it is claimed for this method that it shows a 50 per cent. saving in cost, while the time required to effect a complete tan is reduced from several months to a few days. In the Groth electrical process the hides are suspended on a frame revolving in a circular vat, filled with ordinary tanning solution. It is claimed for the Groth process that it is the cheaper of the two, which is on the face of it very possible, since, instead of a heavy drum full of hides and liquid being continuously rotated, as in the Worms and Balé method, only a comparatively light framework is revolved; moreover, no addition to the ordinary tanning solution is required. Whether the Groth process is more effective, as is claimed, or even equally effective, is a question which will doubtless soon be settled by practical tanners. Meanwhile, whatever may be the respective merits of the two processes, there seems every probability that the value of the patents will be determined—as usual—in the Law Courts.

According to our Copenhagen correspondent, the General Telephone Company of Stockholm intends to start a separate class of cheap subscribers, whose annual subscription will be covered by the modest sum of 50kr., or about £2. 15s. 6d. It is hardly necessary to say that those who pay this reduced charge are not to be served as quickly as ordinary subscribers, and that they are only to be allowed a limited number of conversations per week. A limitation of the number of "calls" allowed might be endured with tolerable equanimity even in London; but a reduction in tariff would scarcely compensate for any further increase in the time at present taken to "switch on." Perhaps a modification of the Stockholm system might be tried here, and the annual subscription made to depend on the average time taken to make the necessary connections.

The technical point of law to which we referred in our issue of November 1st as delaying any further operations on the part of the two electric supply companies at Newcastle, is one which will doubtless be thoroughly appreciated by the legal humourist. It seems that the Town Clerk of Newcastle, while engaged in a refreshing study of the Electric Lighting Acts of 1882 and 1888, has made the interesting discovery that although there are certain penalties attached to the offence of neglecting to repair the streets which have been disturbed by the work of cable-laying, yet there is no authority that has power to set the law in motion. The question was immediately laid before the Board of Trade, who passed it on to their legal advisers for solution, and it has been decided that it will be necessary to amend the Acts. Meanwhile the licences are withheld.

The Editor of the *Revista de Telegrafos* writes us to the effect that there was no foundation for the report to which we alluded in our issue of October 18th, that a criminal had recently been executed at Ossuna, in Andalusia, owing to the delay on the Spanish land lines causing the announcement of his reprieve to arrive too late. No telegraphic reprieve was ever despatched, says our informant; consequently it could not arrive too late.

Digitized by Google

York.—The Corporation have decided to apply for an electric lighting Provisional Order.

Great Yarmouth.—The Corporation intend applying for an electric lighting Provisional Order.

Newcastle-under-Lyme.—The Corporation intend to apply for an electric lighting Provisional Order.

Dover.—The Town Council have resolved to apply for a Provisional Order for lighting the town by electricity.

The Cardew Voltmeter.—This well-known instrument is now being manufactured, under license, by the Edison-Swan Company.

Edinburgh Exhibition.—Mr. A. Bryson, M.I.E.E., has been appointed engineer and electrician to the Edinburgh Electrical Exhibition.

Wrexham.—The Town Council has decided to give consent, upon conditions, to the introduction of the electric light into the borough.

Formosa.—According to the British Consul at Tamsui, the new city of Tai-pei Fu, the capital of the island of Formosa, is lighted by electricity.

Japanese Enterprise.—Applications have been made for 12,000 shares in the Nippon Electric Light Company, Tokio, although only 4,000 are available for allotment.

Burton-upon-Trent.—At a special meeting of the Town Council, held on Monday last, it was decided that the Corporation should apply for an electric lighting Provisional Order.

Electric Lighting Provisional Orders.—The Board of Trade have, it is stated, already received over 300 applications for Provisional Orders for the electric lighting of various towns in Great Britain.

National Telephone Electrical Society.—On Friday evening last Mr. Alfred Coleman, M.I.E.E., delivered an inaugural address, on "The Future of the Telephone," at 40, Bennett's-hill, Birmingham.

Windsor.—The Corporation have given their consent to the applications for Provisional Orders of the Windsor and Eton Electric Light Company and the South of England House-to-House Electricity Company.

Ventnor.—At the last week's meeting of the Local Board, it was unanimously decided to offer every opposition to any electric lighting company who might seek for lighting powers within the area of the Board.

Nottingham.—At a special meeting of the Town Council on Monday last, the report of the Electric Lighting Committee, recommending that the Corporation should apply for a Provisional Order, was formally approved of.

Tunstall.—At the last meeting of the Local Board it was decided to oppose the applications of the Electric Trust Company and of the Municipal Electric Light and Power Corporation unless satisfactory terms were obtained.

West Bromwich.—The Gas Committee's report recommending that an electric lighting Provisional Order should be applied for, and that the sum of £20,000 should be raised to carry out the necessary works, has been unanimously adopted.

Birkenhead.—At a special meeting of the Town Council held on Wednesday last the Parliamentary Committee was authorised to take all the necessary steps to obtain a Provisional Order empowering the Corporation to supply the electric light to the borough.

Bournemouth.—The Bournemouth Improvement Commissioners have given their consent to the applications for Provisional Orders of the Anglo-American Brush Electric Corporation and the South of England House-to-House Electric Supply Company.

Edinburgh.—At a special meeting of the Edinburgh Town Council held on Monday a motion was carried by a small majority that it be resolved to apply for power to introduce electric lighting into the city when the legal difficulty now in the way has been removed.

Gravesend.—At a meeting of the Town Council on Tuesday consent was given to the applications of the Municipal Electric Power and Lighting Corporation, the South of England House-to-House Electricity Company, and the Electric Construction and Maintenance Company.

The Polytechnic.—There is to be an Exhibition at this Institution on Boxing Day, December 26th, of work executed by London apprentices, for which silver and bronze medals and money prizes are to be given. The Exhibition will remain open till January 11th. Further particulars are given in our advertisement pages.

Society of Arts.—The opening meeting of the Society of Arts will be held on Wednesday evening next, when an address will be delivered by the Duke of Abercorn, C.B., Chairman of Council. The second series of Cantor Lectures, to be delivered on January 20th and 27th, and February 3rd and 10th, is on "The Electro magnet," the lecturer being Professor Silvanus Thompson.

Sale by Auction.—On Friday next, November 22nd, Messrs. Chadwick and Sons will sell by auction at their gallery, 35, St. Martin's-lane, London, W.C., a complete electric lighting plant of 1,500 lights, Messrs. Gatti, of 436, Strand, who have had the installation at work, having decided to put down a much larger plant. Further particulars will be found in our advertisement columns.

Mason College Engineering Society.—The annual meeting of this Society was held on October 30th. We are glad to hear that the Society is in a very satisfactory condition, both financially and as regards the nature and technical value of the Papers that have been read and discussed during the past year. After the election of officers for the ensuing year a Paper was read by Mr. E. L. Joseph, entitled "Electrical Novelties at the 1889 Birmingham Exhibition."

Institution of Electrical Engineers Students' Meeting.—The first meeting of the latter part of the Session took place on Friday evening last, Mr. Dykes in the chair. An instructive discussion took place on "The Different Systems of Distribution Employed in London at the Present Time," in which the following gentlemen took part:—The Chairman, and Messrs. Barton, Childs, Horn, Jacob, Müller, Poynton, and Walker. The next meeting will be held on Friday, November 22nd.

Telpher Line at Tirupati.—The Mohant, says the *Indian Engineer*, has long had a telephone line in work, and this has proved of great use in conveying messages to and from Upper and Lower Tirupati. So well pleased has he been with the result of this enterprise that a scheme has now been arranged for fixing a telpher line. The cars will be available for either passenger or luggage traffic at a nominal charge, the time occupied in transit from Lower Tirupati to the site of the temple being calculated at only about 45 minutes.

Dublin.—The Corporation of this city have not yet received from the Board of Trade the permission applied for to supply electricity for private lighting purposes. The Tramways Company and the Alliance Gas Company are opposing the application of the Corporation to the Board of Trade, with a view of getting clauses inserted guarding their interests. The Corporation have not yet decided on a site for their electrical depôt, but as they have at least two of their own available, no difficulty on this head can arise.

Rome.—According to the Rome correspondent of the *Standard* a contract has been signed between the Commune of Rome and the Anglo-Roman Gas Society for the illumination of Rome and the suburbs by electric light. One hundred and sixty-seven electric lights will take the place of 706 gas lights, at an increased expense of nearly 26,000fr. annually. The contract provides that the whole of the works for the complete illumination of the city and suburbs shall be in working order in one year and eleven months from now.

Leamington.—At the last meeting of the Corporation the Watch and Lighting Committee recommended the continuance of the engagement with the Midland Electric Lighting and Power Company, subject to a quarter's notice on either side on

Digitized by Google

any quarter day. It is stated that Messrs. Chamberlain and Hookham have offered to erect a number of arc lamps on the Parade in lieu of the small lamps now in use, and to effect other improvements, and this has influenced the Corporation in withdrawing the notice to terminate the contract, which would have expired at Christmas.

"The India Rubber World and Electrical Trades Review."—This is the title of the latest American addition to the ranks of the technical journals. The first number of the *India Rubber World* is a distinctly good one, containing, as it does, more than 20 pages of very readable reading matter. We note in the customary editorial proclamation on the first page the satisfactory announcement that the *India Rubber World* intends to devote its special attention "to that important branch of electrical development which has been most neglected and most needs improvement, namely, the intelligent and progressive *mechanical* adaptation of electricity."

Berlin.—The report of the *Berliner Electricitätswerke* for the year ending June 30, 1889, shows that this Company continues to make very satisfactory progress. The net profits for the year 1888-89 amount to £26,300, against £14,120 for 1887-88, the gross receipts being respectively £57,300 and £31,840. In 1886 the Company supplied current to 12,000 incandescents and 36 arcs. By the middle of last year the number of incandescents had risen to 37,460, and by June, 1889, the incandescents numbered 46,710 and the arcs 144. It is anticipated that current will be supplied during the coming winter to 60,000 incandescents, and also to a large number of motors.

Tenders Open.—For the supply of the following articles during six months ending June 30, 1890, delivered carriage paid at the Stores, at York, for the North-Eastern Railway Company:—1. Telegraph apparatus. 2. Telegraph wire and line stores. Payment for each month's delivery will be made at the end of three clear months, or in cash less 2½ per cent. discount. Forms of tender may be obtained on application. For the supply of creosoted Swedish or Norwegian fir poles of stout specification for delivery in Scotland during next six months, for the National Telephone Company. Particulars may be obtained on application to the Secretary of the Company, Oxford-court, Cannon-street, London.

The Thomson-Houston System of Electric Traction.—We are informed by Messrs. Laing, Wharton, and Down that they have made arrangements for the "energetic introduction" of the Thomson-Houston system of electric traction into this country, and that Mr. Graff Baker has undertaken the personal management of this department. A system which in America is at work on 53 lines, and will shortly be in operation on 25 more, certainly merits the attention of our tramway companies. Messrs. Laing, Wharton, and Down have also issued a well-illustrated pamphlet describing the advantages of electric traction, and containing numerous testimonials from the presidents of American street railway companies and others.

Stoke-on-Trent.—A special meeting of the Town Council was held on Thursday last week to consider the question of electric lighting. Notices had been received from two companies. In moving that the consent of the Corporation should not be given to such Provisional Orders, Alderman Leason said that the town possessed a gasworks for which the rates were liable to the extent of £67,000. It therefore behoved the Council to resist the efforts of outsiders to come into the borough for the purpose of depreciating the value of their property. He thought it would be advisable for the Corporation themselves to apply for a Provisional Order empowering them to supply electricity, and this, while keeping away outsiders, would give them an opportunity of considering whether they should extend the gasworks or light the congested parts of the town by electricity. The motion was carried unanimously.

Exports of Electrical Apparatus, &c.—The Board of Trade Returns for October show that the smaller exports of the last few months, compared with the corresponding periods of 1888 and 1887, were followed by a very considerable movement last month. The total exports of telegraphic wires and apparatus connected therewith from January 1st to October 31st have been twice as large, judged by value, as the corresponding exports last year, and have been much heavier than in 1887. The following is a comparative statement for the past three years:—

	1887.	1888.	1889.
Jan. 1st to June 30th	£188,812	£244,213	£576,456
July 1st to Sept. 30th	468,252	152,926	117,460
October	31,475	17,938	205,603
Ten months	£688,539	£415,077	£899,519

There appears to be an error in the addition of the 1888 figures given in the Board of Trade Returns. The monthly figures give a total of £415,077, and not £414,177, as given in the Return.

The New Works of the Electric Construction Corporation at Wolverhampton.—The contract for £40,000 to erect the new works of the Electric Construction Corporation, at Bushbury, near Wolverhampton, has been secured by Mr. Henry Lovatt. The site consists of about 24 acres of land. A siding will connect the works with the London and North-Western Railway, and the buildings, which will cover between four and five acres of ground, are so devised that they can be extended without interfering with the operations of the workmen or the roofs of the different structures. The offices will contain board room, consulting room, telephone room, photographing room, two rooms for clerks and draughtsmen, three waiting rooms, and apartments for the secretary and manager. The manufacturing buildings will include machine shop, 300ft. by 90ft.; five erecting shops, 300ft. by 30ft.; foundry, 160ft. by 80ft.; brass-foundry, 65ft. by 40ft.; blacksmith's shop, 84ft. by 30ft.; pattern shop and stores, each 100ft. by 32ft.; chemical laboratory, 60ft. by 20ft.; together with other buildings. The buildings will be erected of Tibbington red brick, with stone strings and facings of blue brick, and the buildings are to be completed within seven months.

A Simple Method of Testing Wire Insulations.—The ordinary method of comparing the value of insulations by determining the insulation resistance in megohms, is, no doubt, the most scientific way, says Mr. H. B. Brooks in the *Electrical World* of New York, but it requires expensive apparatus and a degree of skill which is not usually found in the average central station staff. The writer has for some time made use of a method which requires hardly any apparatus, provided access may be had to an E.M.F. of from 100 to 200 volts. Samples of the wires to be tested are measured off in equal lengths, say 5ft. each. Commencing at a point about 6in. from one end, a bare copper wire is wound on over the insulation in an open spiral, ending at a point about 6in. from the other end. At this point a knot is tied in the bare wire to prevent its sliding or uncoiling, and about a foot of it is left for a connection. About half an inch of the insulation is removed from one end of the test wire. Each wire having been thus prepared is doubled up several times, so that it may be placed in a glass jar, with the portions at each end not covered by the spiraled wire situated above the water line. Water is then poured into the jars, and the end of the outside spiral is connected direct to one pole of a dynamo, and the copper core inside the insulation is connected through a piece of fine fuse wire to the other. The time of turning on current is then noted, and also the time when each wire "leaks" enough to burn off its safety fuse. This is a simple and practical way of comparing insulations by exposing them to the same kind of strain they receive in practice, but more severe. In a recent test made by the writer, "undertaker's" wire lasted about 40 hours; a cheap line wire nearly the same time; a good line wire 275 hours, and a still higher grade of wire 895 hours.

American Electrical Apparatus in the Transvaal.—We have been informed, says the *Engineering and Mining Journal* of New York, that the Forbes Reef Gold Mining Company, of Transvaal, South Africa, have recently ordered from the Sprague Electric Railway and Motor Company, of New York, through Messrs. Chester and Gibb, mining engineers, of London, a complete electrical equipment, including four Sprague long-distance transmission motors and three dynamos, for transmitting 140 horse-power over a distance of three miles. The

Digitized by Google

primal source of power is a waterfall, situated three miles distant from the mine; at this point will be placed three Pelton wheels, provided by Frazer and Chalmers, of Chicago. To each of two of these wheels will be belted one far-transmission constant-potential 50-kilowatt Edison dynamo. To the other wheel will be belted a dynamo of the same type and voltage as the others, but of 40,000 watts capacity. These dynamos are similar in appearance to the standard Edison dynamo for incandescent lighting, and are built at the Edison Machine Works, but their winding is especially adapted according to the Sprague method for the work of long-distance transmission of power. The wires, which are insulated, will be carried overland across country on wooden poles to the point of distribution where are located the four long-distance transmission motors of the constant-potential type, one of 80 and three of 20 horse-power capacity each. These motors are divided into two groups, one single 20 horse-power motor forming one group, and the other two 20 horse-power motors and the 80 horse-power motor forming the other group. Each group is supplied with current by a separate set of wires. The efficiency of the entire system, from the turbine pulley to the mining machines at the farther end, is about 70 per cent.

Ventilating Electrical Conduits.—In view of the difficulties which the New York Board of Electrical Control is meeting in the construction of underground conduits, it is interesting to note a device which has successfully prevented the explosions which at present form such a prominent feature in New York, and which were at one time equally troublesome in Chicago. After considerable experimenting, a system of ventilation was adopted which was the result of the combined efforts of Prof. Barrett and his assistant, David M. Hyland, and the arrangement is now in operation in the basement of the city building at Chicago. The tunnel from the main conduit of the system carries the necessary conductors to the building. This conduit opens into a chamber provided with an air-inlet and a vent connected with a flue, and so arranged that all objectionable gases coming through the tunnel are carried up the flue. The cables are carried through the sides of the chamber in any convenient manner, all spaces about the cables as they pass through the walls being practically air-tight, so that there may be no escape of gas into the building. The flue is preferably one of a stack of chimneys, so that it may be heated, causing a strong draught of air through the chamber. The gas in the conduits is thus caused to circulate, and dangers from explosions throughout the system, as well as in the building, are avoided. It is of importance to cause the gases throughout the system of conduits to circulate, since they are usually of such specific gravity that ventilation at the manholes does not have the desired effect. This simple device is applied to the Chicago system of underground conduits, and not only prevents the explosions in the building, for which it was specially designed, but is also beneficial throughout the system, no explosions having taken place at the manholes or at other buildings connected with the same system since its application, and the injury to the cables heretofore caused by the action of the gases has practically ceased. A somewhat similar device is also employed at Brooklyn with marked success.

The Electrolysis of Distilled Water.—The following is abstracted from the graduating thesis of Mr. M. E. Duler, of Cornell University:—"In these researches I employed distilled water contained in glass tubes with two branches, which, after several months, imparted no alkaline character to the water. The electromotive force used was about 100 volts. As electrodes—(1), an anode and cathode of platinum; (2) anodes of very different metals, principally nickel, cobalt, iron, copper, cathode of platinum; (3) anode of platinum, the cathode of tin, bismuth, copper, lead, mercury, aluminium, &c. In the first case, with a cathode of fine wire, the anode being a large plate, the electrolysis of the water gives off only hydrogen for several days. In the second the anodes are attacked, and at first give off protoxides, forming a substance at the positive poles, which is green with nickel, pink with cobalt, and blue with copper; after several hours the protoxides change to peroxides. If continued for several months, the oxide at the positive pole becomes partially reduced; thus peroxide of nickel forms protoxide, becoming green; that of cobalt, which was maroon, becomes pink; and that of iron loses its reddish colour, and turns almost white. These actions are comparable to those produced on certain peroxides by oxygenated water. In the third case, the negative electrode becomes oxidised. A negative electrode of copper becomes covered with a deposit that almost stops the passage of the current, even using 120 volts. Lead becomes covered with gray tufts, giving rise to protoxide of lead, which seems to flow from the electrode like white pulp. With mercury as the negative electrode, the free surface becomes covered with pasty protuberances having the brilliancy of mercury; these give off hydrogen, and more than an hour after the cessation of the current they give off more. Aluminium is violently attacked, changes into alumina, loses all cohesion and falls to the bottom of the vessel in gray flakes and dust. These experiments, and especially that relating to aluminium, lead me to the conclusion that metallic hydrures are formed at the negative pole, which the water destroys upon the formation of oxide and the liberation of hydrogen."

The Mariner's Compass—Historical.—Although a knowledge of the directive powers of the loadstone was, it is believed, known to the Greeks and Romans, they certainly made no practical use of it. It was, however, known in China, as well as throughout the East generally, at a very remote period. In fact, the Chinese claim that it was discovered B.C. 2634. Humboldt, in his "Cosmos," says that a thousand years before our era the Chinese had already magnetic carriages, on which the movable arm of the figure of a man continually pointed to the south, as a guide to find the way across the boundless grass plains of Tartary. At any rate, 700 years before the use of the mariner's compass in the European seas, Chinese vessels navigated the Indian Ocean under the direction of magnetic needles pointing to the south. The story that Marco Polo first brought the compass to Europe was long ago disproved, since it is clearly shown that the instrument had been used in European seas about 60 or 70 years prior to the time Marco Polo set forth on his journeyings. Humboldt considers it probable that Europe owes the use of the compass to the Arabs, and that they, in turn, were indebted for it to the Chinese. The first allusion to the mariner's compass in any English work occurred in Alexander Neckham's "Treatise on Things Pertaining to Ships," published some time during the close of the 12th century. The earliest mention of the use of the instrument occurs in a poem by Guyot of Provence, in 1190. About 1260, Brunetto Latine notes that the needle was very useful at sea, and calls attention to the unreasonable prejudices which deterred the navigators from adopting it generally. Raymond Lully, of Majorca, in 1286, made the statement that the seamen of his time employed the "magnetic needle." In the reign of Edward III. the magnet was known by the name of sail-stone, or adamant, and the compass was called the sailing-needle or dial. A ship named the "Plenty" sailed from Hull in 1338, and was steered by the sailing-stone. Chaucer, who died in 1400, mentions the compass, and states that sailors reckon 32 points of the horizon, which is the present division of the card. In the beginning of the 14th century, Flavio Gioia, of Amalphi, made a great improvement in the instrument by the simple device of suspending the needle on a centre and inclosing it within a box, and this is how he came to be considered as the inventor of the mariner's compass. The compass used by mariners in the 12th and 13th centuries was very uncertain and unsatisfactory, and consisted simply of a magnetic needle floating in a basin by means of two straws or a small piece of cork. Flavio Gioia's improvement brought the compass into general use. Since that time it has been gradually improved and perfected, and most of the improvements and discoveries in this direction have been made by Englishmen. Thus, R. Norman, of Wapping, discovered the inclination of the needle. The declination, or variation, was discovered by Stephen Burrnars, of Limehouse, and Gillebrand, of Gresham College, made the first accurate determination of this quantity. The first variation chart is due to Halley. Coming down to more recent times, the names of Flinders, Barlow, Airy, Evans, Smith, Napier, Rendell, Towson, and Thomson occur as men who have devoted much time and study to improving such an apparently simple instrument as the marine compass.

SIR WILLIAM THOMSON'S CHAIN OF ELECTROSTATIC VOLTMETERS.

BY ANDREW W. MEIKLE, M.A.

(*Continued from page 7.*)

The sensibility required for the different ranges of the multicellular voltmeter is obtained by varying the number of cells and vanes, the cross-section of the suspending wire, and also the length of wire used. At first a little difficulty was experienced in obtaining constancy in the wire suspension, and a little trouble was consequently given by having to reset the zero from time to time. This difficulty was caused most probably by the straining of the wire in the process of drawing, so that some little time elapsed before it came to a normal condition. A very carefully drawn iridio-platinum wire is now used, and is subjected to a preliminary tempering (*ageing*) by heat, longitudinal tension, and torsion. The results with this suspension have been most satisfactory, and the standard instruments which are constantly in use now give no trouble from changes of zero.

Standardising of the Multicellular Voltmeters.

For low potentials the instruments are graduated by joining their terminals to those of a standard anti-inductive resistance through which a current, measured by one of Sir William Thomson's standard Centi-ampere Balances, is passed. The arrangement is shown diagramatically in Fig. 4. A rheotsat of platinoid wire is joined up in the circuit, in order to vary the current to any desired value. The standard resistance used

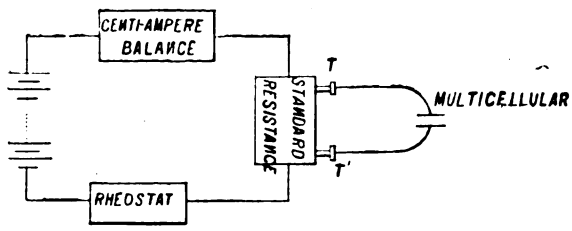

Fig. 4.

is wound with platinoid wire, and its temperature variation is very nearly one-fortieth per cent. per degree centigrade, so that any uncertainty in the estimation of the temperature may be neglected. The Centi-ampere Balance is the standard used in the Physical Laboratory of Glasgow University, and its accuracy is certainly within one-fifteen per cent. These particulars are given simply to show that uncertainties in the standardising apparatus have been as far as possible removed. The Multicellular is joined up to the terminals T T′ of the standard resistance, and shows the difference of potential between them, which at any one time is equal to C × R, where C = current through the resistance as shown on the balance, and R = value in ohms of the standard resistance.

The number of ohms in the standard resistance is varied from time to time so that the deflection on the balance may be sufficiently large to enable any possible error in the reading of the position of the weight to be so extremely small as to be neglected. By this method, and using the battery power at our disposal, it is possible to push the graduation of the instruments up to 140 volts with great accuracy.

For ranges above this point a volta pile is used to augment the potential, as shown in Fig. 5. This pile consists of zinc-copper couples fixed to a vulcanite frame in such a manner that when their extremities are dipped in water the liquid is drawn up by capillary action, and a chain of little cells is formed, each of which gives about 0·9 volt. These volta piles are made up in sets of 200 couples, and the stand containing each set measures about 50 by 10 centimetres. We have found them to give excellent results, and can by those we have obtain over 1,000 volts. The zinc end of the pile is joined to the positive terminal T of the standard resistance, and a voltmeter, A, formerly graduated by the method explained above, is joined up to the same terminal and to a point in the pile such that it gives a convenient reading on a sensitive part of its scale—say, for example, 100 volts. Another voltmeter, B, also graduated to 140 volts, and whose graduation it is wished to extend, is then joined to the other terminal, T_1, of the standard resistance and the same point of the pile as A. The Multicellular B then measures the difference of potential between the terminals of the standard resistance *plus* the difference of potential due to the portion of the pile measured by the Multicellular A. By this means the graduation of Multicellular B may be pushed up to 240 volts. By substituting Multicellular B for A and using it to measure a higher number of volts, a third instrument can be graduated up to 380 volts, and so on. By this means a chain of standards has been obtained giving readings on sensitive portions of their scales throughout the entire range, so that instruments

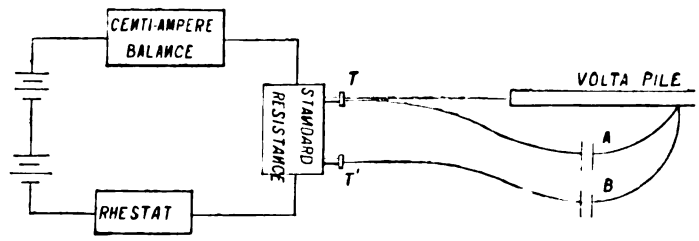

Fig. 5.

can now be graduated by direct comparison; but two of a lower grade, X and Y, joined in series as shown in Fig. 6, are always used in the graduation of a higher range instrument, Z, so that their indications may be amply sensitive as compared with the one being standardised. These standards of course undergo periodical checkings, and are constantly being compared one with another to make sure that they have not been injured in any way since their calibration.

These voltmeters have now been in use in the Physical Laboratory of Glasgow University for some time, and have proved a great convenience, as for many purposes they save a large expenditure of time which would be taken up in making temperature corrections, calculations, &c., were other voltmeters used. We have been able by using them to determine by direct experiment how far other voltmeters could be relied upon to give accurate measurements on alternating circuits under varying conditions, as to period, temperature, &c. The instruments, in

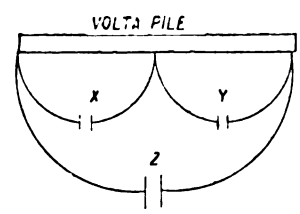

Fig. 6.

conjunction with the volta pile, have also proved very useful in standardising the electrometers used in the investigation of atmospheric electricity, by Messrs. Maclean and Goto, on which a preliminary note was communicated by Sir William Thomson to the British Association (*The Electrician*, September 20th, p. 500).

The Electrostatic Balance.

The arrangement of the parts of this instrument is shown in Fig. 7. The first portion of the condenser in this instrument is a brass disc, B, which is supported from a slate base-plate, S, on three glass pillars, P. The disc is provided with the well-known Thomson "hole slot and plane" arrangement, so that it always rests in exactly the same position on its supports.

A wire thickly covered with india-rubber passes from a terminal, T, through a glass tube, C, C, and makes connection with the disc by a spring contact; this glass tube being filled with paraffin to prevent the lodgment of moisture and give

Digitized by Google

great resistance to disruptive discharge. A sheath formed by a short piece of glass tube pulls up over the terminal T, and protects it from being touched by accident. The slate base-plate is provided with three screw levelling feet.

A brass case fits upon the slate base-plate, and fixed to its top is a metal scale with a glass front which contains the indicator and scale. The movable part V is a square aluminium plate, supported by two long links which pass through a slit in the top plate of the case to two knife-edge stirrups on one end of the counterpoised indicator I. The whole movable portion is supported by knife edges on two brass pillars, and has a short arm, A, with a knife-edge stirrup at its extremity attached to its axis. The weights which fix the constant of the instrument hang on this stirrup.

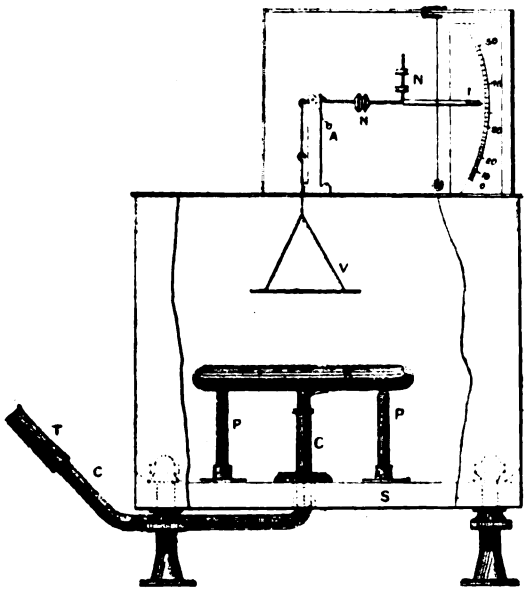

FIG. 7.—The Electrostatic Balance

The instrument is usually graduated by direct comparison with a standard Vertical Scale Voltmeter, and has a scale with divisions corresponding to equal differences of potential. The scale is graduated from 0 to 50, and three weights are provided, such that, with the first alone hung on, the constant is 250 volts per division, with the first and second weights on it is 500 volts per division, and with all three weights on 1,000 volts per division.

(To be continued.)

ELECTRIC TRACTION ON THE BARKING ROAD.

At the invitation of the directors of the Electric Traction Company and the North Metropolitan Tramway Company we recently visited the installation at Barking, and by the courtesy of Mr. Macpherson, the managing director of the Traction Company, and Mr. Thomas Frazer, the managing engineer, we are enabled to give an account of what is being done there.

As our readers are aware, a small section of line is being worked under contract with the Electric Traction Company, by means of cars carrying accumulators. The contract price is 4½d. per car mile, which price includes the driver's wages. The North Metropolitan Company estimate the cost of working similar cars (accommodating 52 passengers) by horses at 5½d. per car mile, so that the saving effected by the use of electric cars is a very substantial one. The total number of car miles which the Traction Company were under contract to perform up to October 31st, was 20,280, while the total actually performed was 19,877—a difference of about 1 per cent. This is a very satisfactory performance when the want of experience in the work is taken into account. We are, therefore, not surprised to learn that the Tramway Company have decided to apply for Parliamentary powers to work all of their systems by electricity.

The cars have the same appearance as ordinary horse cars. The batteries are carried underneath the seats, and are accessible from the outside; flaps or doors running half the length of the car, and hinged at the top, serving to cover in the cells, and give the car the ordinary appearance when on the road. Each car carries two batteries of 48 cells, or 96 cells in all. The cells are arranged on 12 trays, six being accommodated under each row of seats. There are thus eight cells on each tray, which are permanently connected up in series, and the terminal leads connected to brass brackets, which are provided at each end of the trays. When the cells are in position in the cars, these brackets rest upon brass contact plates, which are fixed on the top of wooden rails, which carry the weight of the trays: the mere act of pushing the trays into position, therefore, makes the necessary connection. The four leads from the batteries are brought together to a compound switch, which constitutes the chief controlling device of the car.

This switch is of very ingenious construction. By the movement of a single key it connects the batteries—either in series or parallel, and with a variable amount of resistance in circuit, with the motor. The key is provided with a handle at right angles to the key shaft, and is passed through a hole in the cover of the switch box. The handle stands horizontally when there is no connection between battery and motor. Suppose the handle to be turned upwards: during the first part of the movement a device is operated which connects the two batteries in parallel; continuing the movement this device becomes by a clever arrangement, disengaged, and a radial contact bar makes the connection with the motor circuit through the whole of the variable resistance. The key can now be rotated several steps further, each step reducing the resistance in circuit until the latter is *nil*: this is the *modus operandi* for starting the car. When sufficient speed is attained, the driver turns the handle back through all the stages mentioned, passing the horizontal position, and on to the other half of its range of motion. As the central position is passed the motor is switched off, the battery connections are altered from parallel to series, and the motor switched on again, the connection being made, as before, first through the whole of the resistance, which is reduced as the handle moves on, to nothing. The sparking is diverted from the contact surfaces proper, and taken on the ends of adjustable pieces of $\frac{5}{16}$in. diameter steel rods, in the newer designs of the switch.

The motor can be connected with the cells in parallel by one move of the handle, and with the whole of the cells in series by an opposite movement. The drivers are the same as have been driving the horse-cars, and it is, therefore, not surprising to hear that some of the difficulties which the Traction Company's engineer have had to contend against have been due to the motors being occasionally switched full on to the series battery, without allowing time for the speed to get up.

The reversal of the motor is effected by means of a separate lever, which changes the brushes. A switch and reversing lever are fitted at each end of the cars. The cars are lighted by means of two 16 candle-power incandescent lamps, and the light is quite sufficient to enable passengers to read with comfort.

A steep incline is encountered where the road crosses one of the main sewers, and after this a long, steady rise has to be dealt with; but the cars are easily able to exceed the speed of the horse-cars on any part of the road when the other traffic permits.

A fully-charged set of cells suffices for half a day's work, or about thirty car-miles. The partially exhausted set of cells is withdrawn, and a newly-charged set installed, in the space of three minutes with ease, as we ourselves witnessed; the time of absence allowed from the track being seven minutes. In order to change the cells the car is stopped just outside the tram depôt, the flap-doors are fastened up, and the car moves on between two rows of benches which are fitted with cross-rails, carrying contact plates, similar to those under the car seats. The rails on the benches and in the cars are of the same height, and the car being adjusted between two sets of rails the trays of cells are readily drawn out on to the benches, and are left ready connected up for charging. The car is now moved on to

Digitized by Google

a set of charged cells, which are as easily pushed off the bench rails into the car, which is now again ready for the track. The whole of the cells are charged up at night, an operation which usually takes about ten hours.

The charging plant consists of a 50 horse-power Immisch dynamo driven by a Davey-Paxman undertype engine. A second engine is already in position, and a second dynamo is in course of construction, so as to duplicate the plant. The coal consumption averages about 20cwt. per night, which, with the figures given by Mr. Frazer, the managing engineer, works out to about 6lb. of coal per electrical horse-power, delivered at the dynamo terminals. A considerable increase in the efficiency of the plant resulted from coating the boilers with silicate cotton, and then lagging.

THE IDENTITY OF LIGHT AND ELECTRICITY.*

BY M. H. HERTZ.

The proposition which I intend to develop to-day is that light is in its essence an electrical phenomenon. Deprive the universe of electricity and there would be no light. Suppress the luminiferous ether and electric and magnetic forces would no longer have effect. Many experiments only mark one stage in the development of this theory, and it is the complete history of the theory, not one of its phases only, that I wish now to trace.

What is light? Since the researches of Young and of Fresnel we know that it is an undulatory motion, we know the speed of the waves and their length, we know that they are transverse waves—in short, we know all the geometrical conditions of the motion. All these facts are absolutely beyond doubt. For the physicist the undulatory theory is, humanly speaking, certain, and everything which results therefrom is also certain. It is certain that space is not a void, but filled with a substance capable of taking up vibration—namely, the ether. But if we possess very clear notions of the geometrical conditions of the phenomena which take place in this substance, their physical nature, on the other hand, is very obscure, and what we know of the properties of the substance itself is full of contradiction. Comparing the luminous waves to sound waves, they were considered elastic; but in fluids we only observe elastic waves under the form of longitudinal waves. Transverse elastic waves are impossible in fluids, the very nature of the substance making them impossible. We are, therefore, obliged to admit that the ether behaves like a solid body. But, again, taking into consideration the motion of the planets, we are obliged to assert that the ether acts as a perfect fluid. These two results are evidently contradictory. Without seeking to gloss over this difficulty, let us pass on to electricity: perhaps the study of its nature will enable us to get over this obstacle.

What is the nature of electricity? The solution of this problem is arduous, and excites interest far beyond the restricted sphere of scientific men. Most of those who put this question do not doubt the actual existence of a substance called electricity, and expect a description and an enumeration of the properties and qualities of this singular substance. For the scientist the problem assumes another aspect. Is there such a thing as electricity? Are not electric phenomena connected with the properties of ether and ponderable matter? The state of our knowledge does not yet permit us to answer this question in the affirmative.

The old double-fluid theory served its purpose well until at the beginning of the present century the reciprocal action of magnets and currents and other newly-discovered phenomena necessitated further extensions of the theory which immediately deprived it of its great simplicity. It was difficult to get out of the magic circle of this theory. It did not lead to truth, but it required a great man to resist the current of scientific opinion. It was necessary to study all these phenomena without preconceived ideas, and to start from what was observed and not from what was read. Such was the path followed by Faraday.

Electric and magnetic forces became for him the only tangible realities, and electricity and magnetism descended to the rank of objects whose existence was very doubtful. Considering "lines of force," as he called them, independently of their cause, he saw in them different conditions of space: tension, whirls, currents. When it was objected that space was empty, and therefore was in a state of absolute repose, he answered, Is space empty? Does not the transmission of light oblige us to consider it as full of matter? Does not the ether which transmits luminous waves experience modifications of condition which we perceive in the form of electric and magnetic phenomena? Is there a relation between these modifications and these vibrations? Are not light waves the scintillation of these lines of force? Such were some of the questions put by Faraday.

One of his principal investigations was to determine whether the transmission of electric and magnetic forces was instantaneous. On this point Faraday arrived at no solution. If he had succeeded in doing so his theory would have triumphed from its birth; the relation between light and electricity would have immediately become so evident that it would have received universal credit. Such an easy and rapid triumph was, however, not to be. Experiment gave no answer to the question, and the theory in vogue did not accord with Faraday's ideas. In affirming that electric forces could exist independently of corresponding fluids he contradicted the system generally believed in at that time. It seemed that a discussion of one or the other of these hypotheses must necessarily be a barren speculation. What admiration, therefore, must we not have for the man who knew how to co-ordinate these two hypotheses which in appearance were very far apart. This man was Maxwell. His work, published in 1865, is known under the title of "The Magnetic Theory of Light."

One cannot study this theory without having at times a feeling that mathematical formulæ possess a life of their own, a special reason. They seem at times more intelligent than ourselves—more intelligent, indeed, than he who establishes them; they tell us more than does the man who discovers them. But such comprehensive formulæ could not have been discovered unless the discoverer had possessed the capacity of seizing upon the slightest particle of truth which Nature allowed him to see. Such a capacity was possessed by Maxwell.

This is the question with which we are concerned. Electricity in movement produces magnetic forces; magnetism in movement produces electric forces; and these effects are only appreciable at great velocities. Hence the idea of velocity enters into the relation which connects electricity and magnetism, and the constant which determines this relation has been found over and over again to be the same as the velocity of light. By anyone, except a disciple of Faraday, this coincidence might be set down to chance, but to such a disciple the reason of this fact is undoubtedly that the same ether transmits light and electricity, and therefore the two velocities which had been determined *could* not be anything else but equal. From Maxwell's time the most important optical constant existed amongst electric formulæ. Maxwell set to work to strengthen the band uniting these two phenomena. He enlarged his formulæ so as to make them embrace at the same time all known phenomena and a large class of hypothetical phenomena. If anyone rejected the Maxwellian theory of electricity, it was no longer necessary for him to admit Maxwell's views on the subject of light. In the same way, if anyone affirmed that light was a phenomenon of an elastic nature, Maxwell's theory of electricity became impossible. But if one studied his system without pre-occupying the mind with the ideas in vogue, it was easy to see that all the parts lent each other mutual support, like the stones of a gigantic arch thrown across the unknown, and uniting two ascertained truths. It is true that the difficult nature of the theory did not permit it to acquire many adherents; but when its meaning was fully grasped, it was followed up to its logical consequences, and the value of its fundamental hypotheses was then fully seen. But for a long time investigations were necessarily confined to a few accessible propositions. The demonstration of the possibility of obtaining light directly from electric or magnetic effects would have been a striking confirmation of the theory. The demonstration of the existence of electric or magnetic undulations propagating themselves in a manner similar to luminous undulations would have been another argument of equal value. It was my good fortune to take part in this latter work, and it is to this circumstance that I owe the honour of addressing you to-day, and you must excuse me if I draw your attention only to my own particular work; but time obliges me to confine myself to one single series of investigations.

Was it really so difficult to say that the propagation of electric forces was not instantaneous? Was it not possible to discharge a Leyden jar and observe if the oscillation of a distant electroscope showed retardation of effect? For a believer of Maxwell's theory it was impossible that such a method of proceeding should succeed, owing to the enormous rapidity of electric transmission. It is impossible to observe the excitation of a magnet, the discharge of a Leyden jar, &c., at anything but a moderate distance, say 10 metres. Now, light and electricity, according to the theory, traverse this space in one thirty-millionth of a second. Now, the time necessary for the discharge of a Leyden jar is infinitely short, but short as it is, it is much too long. Nature, however, supplies another method. It has for long been known that on the discharge of a Leyden jar electric oscillations take place. A single vibration can, therefore, be chosen as a sort of unit. Unfortunately, the shortest vibrations observed are of the order of a million a second; therefore the effect of one of these vibrations is propagated to a distance of 300 metres during its existence,

* Abstract of an address to the Congress of German Naturalists, Heidelberg, September, 1889.

Digitized by Google

and it follows that in the restricted space of a laboratory cause and effect will be simultaneous. Another method was, therefore, required, and the obstacle was finally overcome, when it was discovered that not only is a Leyden jar discharge oscillatory, but that oscillations take place in any conductor in the vicinity, and that these oscillations are far more rapid than those of the Leyden jar, being of the order of from 100 to 1,000 million per second. From that time we possessed signals whose duration was comparable with a thirty-millionth of a second, but they would, however, have been of little use to us if we had been unable to seize them, so to speak, only at this distance of about 10 metres. The means we employed were very simple.

At the spot where we wished to observe the signal we placed a conductor—for example, a rectilinear metallic wire, containing a slight interruption; and when the electric field varied rapidly a slight spark appeared at the gap. The sparks are microscopic, hardly the hundredth of a millimetre in length. Their duration is less than a millionth of a second. It seems almost inconceivable that they should be visible, yet they are, in a dark room and to an experienced eye. At the commencement we had a number of questions to solve as to the circumstances under which the vibrations were strongest, the shape to give the conductor, the position to place it in, &c. When these questions were solved the solution of the problem was quite easy.

We observed that at certain points of the room sparking was violent, while at others it was extinguished, and we noticed that places of electric activity and inactivity succeeded each other in regular order, and we were able, therefore, to affirm that the propagation was not instantaneous, and we were able to measure the wave lengths. Were the waves longitudinal or transverse? In reply to this query we placed our wire in two different positions at the same spot. In one it showed electric excitation, in the other not. This decided the question: the waves were transverse. What was the speed of propagation? It was only necessary to multiply the wave length by the duration of the vibration, which we could calculate. We found a velocity approximating that of light. If you contest the exactitude of our calculation, we have another resource. The velocity of electricity in long wires has for long been experimentally determined, and we found that it agreed very well with that obtained by us in these experiments. These experiments, simple as they are, have important bearings: they overthrow the whole theory of action at a distance, and mark the triumph of Maxwell's system.

To those who still doubt I would point out that every effect which is observed with light waves can be observed with these electric waves. If the conductor is placed in the focus of a large concave mirror, the electric waves unite and leave the mirror in the form of a rectilinear pencil. By turning this mirror we can send the ray in a different direction. When we interpose in its path conducting bodies, the electric ray is stopped, but not destroyed, since it is reflected. To study the refraction of light we employ a prism. The same can be done for electricity, only the dimensions of the waves and of the ray oblige us to use as a conductor a very large prism. Moreover, it is necessary to choose a cheap substance, such as pitch or asphalte. Finally, it is possible to observe with the electric ray phenomena which up to the present have only been observed in the case of light, namely, those of polarisation.

But enough of experiments. In future we must not speak of currents traversing conductors: we must speak only of undulations crossing space, separating, assisting each other, or reinforcing each other. The domain of optics is no longer limited to undulations only a fraction of a millimetre in length: it comprises waves whose length may be measured in decimetres, metres, and kilometres. From now electricity will be seen in many places where it was not previously suspected. The domain of electricity extends over the whole of Nature. But there are questions behind which still remain unsolved—the questions of the nature and property of matter, of the ether, its structure, movements, and limits. Still further behind this is the question of weight and inertia. Physicists of ancient days decided that everything was made of fire or water. Before long the modern physicist will ask if all existing things are not modifications of the ether. That is the final goal of modern science. Shall we ever attain it? To that question I can give no answer; but we have got to a higher point than we have ever attained before, and the road is not too steep, and the next stage is not inaccessible. Numerous ardent spirits are pushing their investigations, and we can await with confidence the result of the searches which are being made in this direction.

Exeter.—The Exeter Electric Light Company ran their arc lamps on Monday last for the first time. Amongst the buildings lighted by arc lamps is the St. Sidwell's Church. The lights at the theatre have lately been running much more satisfactorily.

LONDON CHAMBER OF COMMERCE.

Special Meeting of the Electrical Trades Section.

A special meeting of the Electrical Trades Section of the London Chamber of Commerce was held on Monday at their offices, Botolph House, Eastcheap, to receive the report of the Committee which was appointed at the meeting on the 28th ult. Mr. R. E. Crompton presided, and among those present were Sir James Anderson, Major Flood Page, Prof. G. Forbes, and Messrs. J. Swinburne, Musgrave Heaphy, J. F. Albright, Stepney Rawson, A. P. Lundberg, A. Le Neve Foster, W. Beaumont, R. S. Erskine, C. J. Wharton, and G. Binswanger. Mr. C. Musgrave, of the London Chamber of Commerce, acted as general secretary at the meeting.

The CHAIRMAN stated that the Committee appointed at the last meeting had met several times, and had prepared a report which Mr. Trotter would read.

Mr. A. P. TROTTER (the Sectional correspondent) read the report, as follows:—

REPORT OF THE SPECIAL COMMITTEE ON THE EDINBURGH EXHIBITION.

At the meeting of the Committee of the Section, which was held on October 28th, the following resolution was proposed by Major FLOOD PAGE, seconded by Mr. SWINBURNE, and carried unanimously:—

Resolution.

"*That with a view of the electrical industry taking common and united action with regard to the proposed Electrical Exhibition in Edinburgh in 1890, a Committee be appointed to consider the conditions on which it may be advisable to take part in the Exhibition, and that a meeting of the Electrical Section of the Chamber be called for Monday, November 11th, to receive the report, and, if thought advisable, to take action thereupon.*"

Your Committee have considered the question referred to them in the above resolution, and have the honour to report as follows:—

1. If the Exhibition Committee in Edinburgh had consulted the electrical trade as to the desirability of holding an Electrical Exhibition in the year 1890, they would probably have received a well-nigh unanimous answer that it was too soon after the Paris Exhibition to serve any useful trade purpose.

2. The opinion of the industry on such a matter can easily be ascertained now that an Electrical Section of the London Chamber of Commerce has been formed, as members from all parts of the kingdom belong to that section.

3. Nevertheless, the Exhibition being in course of organisation, it seems advisable that the trade should not refrain from exhibiting, provided that terms can be obtained from the Exhibition authorities more favourable to the trade than those provided in the regulations which have been issued.

4. It must be clearly understood that this report is not dealing with the question of lighting the Exhibition, for which, of course, the Exhibition authorities must pay in the usual manner; nor with any question involving the purchase or hire of any electrical plant which the Exhibition authorities may require for their own purposes; but simply with the question of exhibitors.

5. The charge for space is to be 2s. 6d. per square foot, the minimum charge being £2. 10s.

We think that the electrical exhibitors should be allowed an agreed-upon space free, and should pay for any additional space they may require.

6. Many of the electrical exhibits, though not intended in any way to light the Exhibition, cannot be properly shown unless they have steam or current supplied. We think that, when steam-power or current is necessary for the proper display of the exhibit, they should be provided by the Exhibition authorities free of cost to the exhibitors.

7. The regulations provide that the exhibitors should furnish all necessary attendants. We recommend that, for electrical exhibits where there is no machinery in motion, the Electrical Section should club together, and appoint and pay for such attendants as they may judge necessary.

8. We think that the Exhibition authorities ought to pay for the insurance of the electrical exhibits.

9. We suggest that there should not be any awards; but if it is determined to have awards, we think that the Council of the Institution of Electrical Engineers and the Electrical Section of the London Chamber of Commerce should recommend the jurymen to the Exhibition authorities.

10. Clause 25 of the regulations is as follows:—"The Executive Council reserve to themselves the right of examining, testing, or analysing any of the exhibits."

Digitized by Google

We do not think that any person whatever except the electrical jury should have the right to test, analyse, or examine (in the sense here meant) any of the electrical exhibits, and we think that any electrical exhibit may be sent without being in competition, and such exhibits should not be tested or analysed even by the jury.

11. In conclusion, although the whole of the electrical trade is now busier than it has ever been, and is certain to be busy all through the year 1890, and much valuable time will be occupied in the preparation for the Edinburgh Exhibition, and although it is not likely that any profit or advantage will accrue to the electrical exhibitors, yet on the whole, as the Queen has given her support to the Exhibition, and Scotland generally seems inclined to do what can be done to make the Exhibition a success, we think that the electrical trade should not "boycott" the Exhibition; but we strongly urge that the permanent Committee of the Section should obtain terms at least as favourable as those indicated above.

12. Your Committee have good reason to believe that well-nigh the entire trade will support such improved and reasonable conditions as we have suggested.

Signed on behalf of the Committee,

ALEX. P. TROTTER, Correspondent.

The CHAIRMAN said that before he called for any resolution to be moved respecting the report, the Committee would be very glad to hear what the trade might have to say on the various points dealt with in it.

In answer to questions the Chairman stated that so far as he was aware, the communications of the Committee had been only with the trade; they had not yet communicated with the Exhibition authorities. Two gentlemen from the Exhibition were at that moment in another room waiting to have an interview with the Committee, but before seeing them the Committee thought it would be best for the members of the Section to make up their minds as to what course should be taken. He presumed that any resolution they might pass at that meeting would only bind those present. A good many of the principal firms, however, were represented on the Committee, and they had received letters from the members of the trade who were unable to attend, and who are all in favour of the project—for instance, Mr. Marshall, Messrs. Mather and Platt, and Mr. Garcke.

Major FLOOD PAGE pointed out that the Special Committee was appointed for the purpose of drawing up a report. They had no power to enter into communications with the Exhibition authorities. That was a matter which would fall to the permanent Committee of the Section. The Section could either adopt or refuse to adopt the report, or part of it, or they could modify it. As soon as that was done the permanent Committee would take up negotiations with the authorities in Edinburgh, based, he supposed, on the report, if the report were approved. He believed it would be quite impossible to bind any trade people. Considering that there were 210 members of the Section the meeting was a small one, but he thought it would have been larger if longer notice could have been given. He thought, however, that the expression of that meeting would carry great weight with it.

Mr. MUSGRAVE HEAPHY quoted paragraph 8 of the report, and said he would rather not express any opinion as to the recommendation that the Exhibition authorities should pay the insurance of the electrical exhibits.

The CHAIRMAN remarked that that was a point upon which they all held a strong opinion, for owing to the bad construction of the buildings at South Kensington, the exhibitors found themselves charged very heavily.

Prof. FORBES said that while the trade would not want a repetition of tests which had been already made, there was a large quantity of electrical machinery which did require tests at the present moment, especially alternating-current machinery. He believed that the Exhibition authorities were thinking of making tests; but it might be a point whether or not the trade should make any representations to them on the subject. In answer to a remark, he added that the deputation that had waited upon the Council of the Institution of Electrical Engineers stated that the Exhibition authorities were quite prepared to go to considerable expense in connection with tests. Many tests were not necessarily required, but he thought that in regard to alternating currents and transformers, tests would be very important.

Major FLOOD PAGE: It depends entirely on who is to make the tests.

Prof. FORBES: Undoubtedly; and the suggestion in your report is a very good one.

Major FLOOD PAGE said that in the report the Committee had suggested that there should be no awards, but that, if awards were made, the Institution of Electrical Engineers and the Electrical Trade Section of the London Chamber of Commerce should be asked to nominate the jury. The value of the awards would depend on who were appointed, and it would also take a long time. The tests went on for nearly three months, he believed, after the Exhibition at the Crystal Palace was closed. It would also involve considerable expenditure. He thought they might take the report as it stood, and consider the suggestion of Prof. Forbes as an additional recommendation; and if that gentleman would assist them in formulating some proposition to the General Committee, it might help the matter forward.

Major FLOOD PAGE then proposed the following resolution:

"That the report of the Special Committee on the Edinburgh Electrical Exhibition be received and adopted, and that the subject be now referred to the Permanent Committee of the Section, with power to negotiate and carry out the necessary arrangements with the Committee of the Edinburgh Electrical Exhibition."

He thought there had been some little misconception as to the duties of the Committee which had made the report. They had really had very little time, and it was necessary that they should have that meeting. In a fortnight, as at present arranged, the entries must go in to the Exhibition. If the meeting passed the resolution he had proposed, it would fall into the hands of the Permanent Committee to enter into negotiations with the Exhibition Committee.

Mr. A. LE NEVE FOSTER seconded the motion, which was adopted.

Mr. ALBRIGHT thought that before seeing the two gentlemen referred to by the Chairman, the meeting should decide as to the question of space which the trade would require at the Exhibition.

Major FLOOD PAGE replied that the question was dealt with in the report. The suggestion, however, of Mr. Albright seemed to him to open up another field of usefulness for the Section. Mr. Kenric Murray (the Secretary of the London Chamber of Commerce) had told him that the West African Section took charge practically of the whole of the West African exhibit at the Colonial Exhibition. The question which arose out of the suggestion of Mr. Albright was whether it would not be an increased advantage for all the exhibitors to exhibit through their Section of the London Chamber of Commerce. One of the rules in connection with the Edinburgh Exhibition was that applicants for space from foreign countries and the Colonies, for which no Commissioner was nominated, must appoint representatives in Scotland. Now, if a Commissioner were nominated, all the entries would go through him, as in the case of the Paris Exhibition. The trade would then secure united action, which they would not get in any other way. At present it was not known what space would be required by the trade, and they therefore had had to make this point vague in the report. He thought if they could arrange to have all the exhibits sent through the Electrical Trades Section of the London Chamber of Commerce it would do a great deal of good.

The CHAIRMAN asked Sir James Anderson if he thought that the telegraph companies would take part to any considerable extent in the Exhibition.

Sir JAMES ANDERSON replied that he had no doubt the telegraph companies would do all they could. He was, however, at a little loss to know what they could show. They had so often taken part in exhibitions. He was at the Paris Exhibition the other day, and he could not find their exhibit, though they had obtained a gold medal for it (laughter). One did not expect an Exhibition so soon after the Paris Exhibition.

The CHAIRMAN: We all feel that. What do you think of treating Scotland as a foreign country, and going under one section?

Sir JAMES ANDERSON: I think you should go under one section, and I do not think Scotland would object to that.

Mr. ALBRIGHT proposed the following resolution:

"That, provided the Edinburgh Exhibition authorities accept the terms as set forth in this day's report, the Electrical Section of the London Chamber of Commerce act generally as Commissioners for the electrical trade at the Edinburgh Exhibition."

Mr. SWINBURNE seconded the motion, which was adopted.

Mr. Lee Bapty, general manager, and Mr. Gaskell Exton, secretary of the London Committee of the Exhibition, were then invited into the meeting, and

The CHAIRMAN gave them a summary of the recommendations contained in the report of the Committee, and mentioned the suggestions which had been made during the meeting.

Mr. LEE BAPTY said he had hoped to have had the opportunity of meeting their Sub-Committee in order to discuss these points before the report had been made to the Committee of the Section, because he had already consulted his Council in Edinburgh, and had been prepared with a certain amount of concession from them, which he had hoped would meet with the views of the Committee. He noticed that the Committee seemed to think that the Exhibition authorities were asking to have the Exhibition lighted for nothing, and that it had been started without consulting the trade in any shape or form. He had only been appointed General Manager of the Exhibition after the whole thing had been decided upon generally, but he had been informed that the project was broached to the electrical and technical press before it was put into a concrete form, and that it had met with their support. The promoters of the scheme in Edinburgh

Digitized by Google

therefore thought they would always have the support of the members of the trade. With respect to the concessions asked for, an objection appeared to have been taken at the last meeting that it was not fair to ask the electrical trade to go to Edinburgh to make money for the promoters of the Exhibition there. Now, that was the last thing the promoters had in view. All that they wanted was to present to their visitors the latest developments of electrical science and industry, and, as a proof of that, he had their authority to offer to all the exhibitors of electrical appliances—all who came with the *cachet* of the Electrical Trades Section of the London Chamber of Commerce—that, after the legal demands were met, any money paid for space by their exhibitors should be returned in full, or as near as the surplus would allow. He hoped that that would meet their views in the matter of having free space, because he thought it was certain that there would be a surplus left. With respect to the payment of insurance, that was a matter that had not cropped up at all, but he would be prepared to ask the Committee of the Exhibition to meet them on that point, which was not a serious matter. It was, however, something that had never been done before.

The CHAIRMAN: The cause of this request is that the exhibitions in London were located in buildings of such a nature that the charges for insurance were very high, and came very heavily on the exhibitors.

Mr. LEE BAPTY stated that at Manchester they had pictures of the value of about £2,500,000, and the insurance was only 7s. 6d. per cent., or 10s. to cover all risks—carriage, breakages, &c.

The CHAIRMAN: If that is so, and you have buildings of that permanent kind, the insurance would not fall so heavily on the exhibitors.

Mr. LEE BAPTY said he did not know how the Exhibition was going to be built, but he believed that at Manchester they reduced the cost of insurance very much by undertaking to pay for efficient watching. He had twenty-four watchmen and six firemen constantly on duty throughout the night, and they never had a single claim during the whole time. With respect to the question of awards, he thought he might say that the Exhibition authorities would leave themselves entirely in the hands of the Trade Committee. As, no doubt, they were aware, the subject was broached at the meeting of the Council of the Institution on the previous Monday, and it appeared to be the feeling then that it would be desirable to have certain trials if the exhibitors wished for them; but he should say that the Exhibition authorities would not be prepared to have trials excepting at the expense of the exhibitors. If exhibitors wished to have trials and competent tests by a technical jury, he thought they would be asked to pay for the charges of the jury. With reference to the regulation quoted in the Committee's report as to the testing, &c., of the exhibits, the rule was not intended to apply to machinery or electrical appliances, but to enable them to reject any intended exhibit which might be dangerous—such as an oil or a spirit. As to the lighting, there had never been any intention on the part of the authorities to ask for the lighting free. They were now preparing specifications for the electric lighting contracts, and they would be sent out in the usual course to all electric lighting firms—those who were prepared to accept such contracts. Steam-power would be provided for the ordinary exhibits. He thought there ought to be no difficulty in finding free current. With reference to the remark about the proposed Exhibition being too soon after the one in Paris, he was afraid it was too late to discuss that matter now, but if the Exhibition authorities had the support of the electrical trade, nothing would be wanting on their part to make the Exhibition a great success. His committee had felt that the improvements in electrical science were sufficient to warrant an Exhibition.

Major FLOOD-PAGE said he thought they might be very much encouraged by what had fallen from Mr. Bapty. One point was of great importance. They were now in the middle of November and the entries would close on December 1st. He supposed the Exhibition authorities would allow the electrical exhibits to be entered until January 1st? He would ask Mr. Bapty formally to consent to that extension, as some time would be required for preparation by those who intended to take part in the Exhibition.

The CHAIRMAN (to Mr. Bapty): I have further to tell you that we cannot take your answer about testing as final. There are some kinds of electrical appliances that would add enormously to the interest of the Exhibition if there were tests. We propose, in the course of a few days, to send you a resolution which we shall draft on the subject; but the pith of it will be that whereas other kinds of machinery have all been tested at other exhibitions, there is one kind that has never been tested—alternating machinery and transformers; and we think it would be a great advantage to the trade, the public, and every one, that a trial should be made, and that that limited amount of testing should be provided by the executive.

Mr. BAPTY supposed that it was only wished to apply the tests in question in cases where the exhibitors voluntarily submitted themselves to the ordeal.

Prof. FORBES stated that when the deputation waited on the Electrical Engineers the other day the question was raised, and it was rather thought that the best plan would be that a selection should be made by competent judges as to what machinery should be tested, assisted by the wishes of the exhibitors.

Mr. BAPTY expressed his obligation to the Committee, and the proceedings then terminated.

THE CITY GUILDS AND TECHNICAL EDUCATION.

It is now about twelve years since some of the leading City Companies determined to draw up a scheme for a national system of Technical Education, which was to be started and maintained out of their Corporate funds. A Committee was formed of members of the companies interested, strengthened by the addition of Sir WILLIAM (now Lord) ARMSTRONG, Mr. BARTLEY, Lieutenant-Colonel DONNELLY, Captain DOUGLAS GALTON, Prof. HUXLEY, and Mr. H. TRUEMAN WOOD. The report presented by this Committee embodied a scheme providing for the foundation in London of a central institution for higher technical instruction, for the establishment and assistance of trade schools, and for the conduct of the examinations in technology, which had been established by the Society of Arts in 1876, with the aid of a grant from the Clothmakers' Company. An Association of Livery Companies, for carrying out these objects, was founded in 1878 under the designation of "The City and Guilds of London Institute for the Advancement of Technical Education." A commencement was made very shortly afterwards by the Association taking over the conduct of the Technological Examinations, and by the appointment of Professors AYRTON and ARMSTRONG to give courses of evening lectures in physics and chemistry respectively, with special regard to their appli-

Digitized by Google

cation to various industries; and these courses, which were first held at the Cowper-street Middle Class Schools, were extended two years later by the appointment of Prof. PERRY to lecture on Mathematics and Engineering. In the same year Mr. (now Sir PHILIP) MAGNUS was appointed Organising Director of the Institute and Secretary to the Council, and in 1883 the classes were transferred to the Finsbury Technical College, which had been specially built for the purpose.

The Finsbury College was intended to provide technical instruction mainly for artisans, of such a kind as to develop their intelligence, and to fit them by so doing and by training them in the scientific principles underlying their work, to improve the methods of manufacture adopted in the trades in which they are engaged, and so effect something towards enabling British workmen to compete with those of other nations under less disadvantageous conditions. Very soon after the opening of the Finsbury College classes were formed for giving special instruction in applied art and in the manipulative details of various trades. These classes have, no doubt, been of considerable assistance to a large number of artisans, who by that means have been enabled to acquire a more thorough knowledge of their trade, and thereby to earn increased wages. It would, however, be nothing less than a disaster if the result were to drive into the background the primary object of the College: to provide workmen with a training adapted to enable them to occupy positions as foremen of works, not merely to their own advantage, but to that of the industry in which they are engaged. That this is not by any means an imaginary danger is clearly shown by some recent press criticisms on the work of the Institute, and by the position taken up with respect to it by several of the members of the City Corporation. To a superficial observer, the trade classes appear to form the most important portion of the work of the Finsbury College, simply because of the large numbers attending them, attracted by the prospect of obtaining higher wages. It is necessary, therefore, to insist strongly on the fact that what these classes do is simply to teach workmen what they ought to have learned during their apprenticeships, and that however much benefit they may be to individual artisans, their usefulness to the nation bears an infinitesimally small ratio to that of educating men capable of introducing new methods and modifying old ones, to the advantage of all who are engaged in the same industry, and therefore to the advantage of the commerce of the country.

An even more important work than the training of intelligent foremen was commenced at the Finsbury College, and transferred to the Central Institution at South Kensington, at its opening in 1884. This consists in the education of mechanical, electrical, and chemical engineers, of so thorough a character as to enable them, after having intelligently gone through the College course, and afterwards obtained a knowledge of the commercial aspects of the industries severally selected by them, to take the lead in the development on scientific—that is to say, on truly practical, lines of the engineering industries of the country. The value of work of this kind is not to be measured merely by the numbers who are trained in this manner—and, indeed, it would not be advisable to turn out men of this kind in any very large numbers, for the simple reason that it would be impossible to find places for them all; and, therefore, as the number of applicants increase beyond what are required, it will be advisable to increase the severity with which the comparatively idle or incompetent are weeded out, so that the advantages offered by the Institution, which is beyond comparison the most fully equipped and the most efficient engineering College in the country, may be given to those who are most capable of profiting by them. Although the Central Institution was only four years old last July, 82 students had attended complete courses of instruction during the preceding session, and 42 had been studying special subjects under the regulation which provides for the admission of students desirous of studying some special branch to the courses of lectures which they require, or to the laboratories, subject to the condition that they shall satisfy the professor at the head of the department in which they wish to study of their having the preliminary knowledge requisite to enable them to profit by the permission. The session which has just commenced shows a still further increase.

In addition to the main work of the Central Institution, most valuable though unobtrusive service is being done to the general cause of Technical Education by the Summer Courses of Lectures given by the Professors and other eminent specialists to the science teachers throughout the country, and 226 students attended these courses during the past session. One of our daily contemporaries recently objected to the fees charged to the regular students of the Institution (£25 to matriculated, and £30 to unmatriculated students) as being too high, and precluding many of those for whom its advantages were intended of availing themselves of them. We, on the other hand, are inclined to agree with the majority of those who send their sons there, and who are almost unanimous in their wonder at the extreme lowness of the fees compared with those which they would have to pay for from three to five years, if their sons were apprenticed to an engineering firm; and students after leaving the Institution, except in cases of exceptional ability, usually find that they have to pay more for their final year, spent in an engineer's workshops, than for their three years at the Institution. On the other hand, the scheme of the Institute provides means by which the poorest, if of sufficient ability, may avail themselves of its advantages, for scholarships tenable at the Finsbury College are offered to meritorious candidates from the Board Schools; and the best of these candidates can afterwards proceed to the Central Institution by means of special scholarships, besides having the chance of competing for open scholarships of greater value.

The work which we have briefly sketched out as being done by the Technical Institute is one of such vast importance to the country, that it is of the utmost importance that it should not be crippled for want of funds, and, therefore, while we are grateful to the City Companies for what they have already done, we would urge them not only to continue their good work, but to do still more than they are doing at present. When the Institute was first founded, it was proposed that all moneys voted by the different Companies should be placed unreservedly at the disposal of the Council, and this was carried out for some years with very great advantage to the cause of technical education. Unfortunately, however, within the past few years several of the Companies, instead of paying their subscriptions into the general fund, have preferred to devote them to the foundation and maintenance of special institutions under their own immediate control. This course has, no doubt, the advantage to the individual Company of producing a more immediate show for the money, but in view of the very great importance of the subject, and of the undeniable fact that incomparably greater good can be done by united efforts than by each Company carrying out its own ideas on its own plan, we trust that public opinion may be directed to the matter, and due credit given to the Companies who have thought more of conferring a lasting benefit on the country than of how much display they could obtain for a given expenditure. And we should at the same time like to see pressure brought to bear on those who have been less disinterested, so that they may be impelled to go and do likewise.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"The Lighting of the Centennial International Exhibition, Melbourne, 1888 and 1889."*

BY K. L. MURRAY, C.E.

In November, 1887, the Executive Commissioners of the Centennial Exhibition, which it had been decided to hold in Melbourne in the following year, consulted me as to the practicability, electrically and commercially, of using electricity as a means of lighting the Exhibition, and I felt that I could assure them that the electric light was the only one which could be depended on to efficiently illuminate the buildings and exhibits, and that its cost would not render its use prohibitive. I recommended dividing the buildings into three sections, and calling for separate tenders for supplying and maintaining the dynamo machines and lamps necessary to light each part, tenderers being requested also to submit an alternative offer for the whole lighting required. My desire was to have each section lighted by a different section, if possible. Finally, I was entrusted with the duty of drawing up a specification, and tenders were invited. Those received all named such a high price for the work that I could not recommend the acceptance of any; but being requested by the Exhibition Commissioners to arrange with one or more of the firms which tendered, I was able eventually to do so, and a contract was entered into with the Australasian Electric Light, Power, and Storage Company for the lighting of the greater portion of the Exhibition buildings, and an agreement was made with Messrs. Ganz and Co. to supply a transformer plant and light the Armament Court, the official reception and dining rooms, and offices.

The Australasian Company's contract was to supply, fit up, and maintain 825 Brush arc lamps, 37 Brush arc dynamos, 7 Brush Victoria dynamos, compound-wound, and 2,000 incandescent lamps, with all requisite switches and fittings. The whole of the machinery and other apparatus was to be of the latest pattern and best workmanship. As usual in such cases, the buildings were ultimately extended considerably beyond the limits originally laid down. The lighting plant had, of course, to be increased proportionately, so that the apparatus actually supplied by the Australasian Company consisted of as under:—

40 Brush arc dynamos, known as No. 7*l*, each capable of giving a current of 10 amperes to from 23 to 25 arc lamps in series.

1 Brush arc dynamo, knows as No. 8*l*, professedly capable of giving current to 55 arc lamps in series.

1 Brush arc dynamo with cast-iron armature, known as No. 6, supplying current of 20 amperes for 5 arc lamps.

7 Brush Victoria dynamos for incandescent lighting, compound-wound for 110 volts at terminals.

937 sixteen-hour round-type Brush arc lamps, with alabastrine globes; 5 Brockie-Pell 20-ampere arc lamps for lighting the dome; 2 Castle arc lamps.

1,900 Swan lamps of 16 candle-power at 100 volts; 27 "Sunbeam" lamps, of sizes ranging from 200 to 600 candle-power each at 100 volts.

All necessary switches, fuses, and leads, the total length of the latter being over 60 miles.

The 7*l* Brush arc dynamos were of two patterns. 1st, that in which the bed-plate and field-magnet yokes are cast in one piece; the field-magnet cores with pole-pieces being, as usual in this form of machine, of cast iron, fastened to the yokes with bolts. The commutator, brushes, and terminals are mounted on a slab of slate, which is fitted into a recess left for it in the bed-plate casting. The other pattern of arc machine has what may be termed a composite bed-plate, or no bed-plate at all. In these machines the two field-magnet yokes are cast in separate pieces, the cores, with pole-pieces, being, as in the former pattern of machine, bolted to the yokes. The two horse-shoe magnets thus formed are connected by two pieces of railway iron, which constitute whatever of bed-plate the machines have. The commutator brushes and terminals are mounted on a slab of wood fitted between the longitudinal pieces of railway iron. The first class of machine will hereinafter be called "solid frame," the latter "rail-pattern" machines. The majority of the solid-frame machines had previously been used at the Adelaide Exhibition, but were fitted with new laminated armatures for use in Melbourne. The balance were sent out direct from England. The framework of the 8*l* dynamo was imported, but the laminated armature was made and all coils were wound in the Australasian Electric Company's workshops, Melbourne. This dynamo was of the solid-frame type. The No. 6 dynamo was also of the solid-frame type, but had a cast-iron armature. Its coils were arranged for a current of 20 amperes. Two types of laminated armature were supplied with the No. 7*l* dynamos—one having plates ·05 of an inch in thickness, the plates of the other being only ·022 of an inch thick. The former I will call thick, and the latter thin plate armatures. The dynamos for incandescent lighting, seven in number, were of the Brush Victoria pattern known as No. E2. The nominal output is stated to be 366 64-watt lamps at an average armature speed of 720 revolutions per minute. The machines were of the newest type, and had very massive magnetic circuits throughout. The armatures are wound with only three layers of rectangular wire, each section consisting of three convolutions. The laminated iron core in the V spaces between the windings is not covered with insulation, so that in these parts it is directly exposed to the cooling influence of the air. The arc lamps were of the well-known Brush 16-hour round type, wound with the low-resistance shunt recently adopted by the makers. Alabastrine globes were used.

In the main annexes the arc lamps were arranged in a double row down each bay, one lamp being allowed for about every 1,200 square feet of floor space. The bays were about 50ft. wide, and the distance between the two rows of lamps was about 25ft., the height of the globe from the floor being about 22ft. Incandescent lamps of 16 candle-power at 100 volts, to the number of about 1,900, were used for illuminating the picture galleries, beneath the galleries, in the aquarium, and in the cellars. The concert hall was lighted by 25 "Sunbeam" lamps of from 200 to 600 nominal candle-power. The incandescent lamps in the picture galleries were set in a single row, 9in. apart, on reflecting frames, the reflecting surfaces of which were painted a dead white. These frames were about 18in. wide, made of sheet metal. Below the lamp another reflector was placed, the primary object of which was to shade the eye from the direct glare of the lamps and keep the floor comparatively dark. With the above arrangement of reflecting frames the walls were the only portions of the galleries illuminated by the direct light from the lamps, and the total absence of glare allowed of a very pleasant rest for the eyes. The switch-board for the arc circuits consisted of two parallel rails of wood, on which ordinary double brass binding screw terminals were fixed. The screws on the lower rail were connected to the dynamo terminals, while those on the upper rail formed the terminals of the various lamp circuits. The positive terminals of all machines and circuits were at one end of their respective rails, and the negative terminals at the other. The connection between the dynamo and circuit terminals was effected by means of short lengths of well-insulated cable. The incandescent switch-board was mounted on a well-finished cedar stand. It consisted of two large slabs of black enamelled slate, on which the nickelled switches and terminals were fastened. Between the two slabs of slate a suitable recess was formed in the woodwork for the reception of a Cardew voltmeter (Goolden and Trotter's make). In the centre of a cedar panel below the voltmeter a small switch was placed, by which any one of the machines could be connected to the voltmeter by turning a handle. Suitable terminals were provided for the introduction of safety fuses, and also for enabling the machines to be coupled in parallel. When so coupled any one or more machines or circuits could be switched on or off without affecting the rest.

The arc circuits mainly consisted of 7/16s stranded cable, nigrite and tape insulated, all other being of the same size of cable, but insulated with rubber and braided. The leads were so arranged that between every two lamps getting current from the same dynamo, there were at least two lamps getting their current from some other dynamos: my object being to make certain that the building should be fairly well lighted, even if several dynamos broke down at the same time. All leads and returns ran in one direction from the dynamo room to the main buildings. But on entering these buildings the leads and returns were taken in totally different directions to the terminal lamps of their respective circuits. By this means, and careful attention to the arrangement of the circuits, the leads and returns never approached each other, except in the dynamo room. Consequently, short-circuiting in the buildings was almost impossible. The lamp circuits were run on the woodwork which carried the roof. The lamps were suspended by cords, so that they could be lowered for carboning or other purpose. The wires from the lamp terminals were taken up the suspending cord and lashed to it at a point a few inches from the pulley when the lamp was at its proper height. They were then taken to the woodwork and fastened to it at such a height that the length of wire forming the cord, together with that from the point of lashing to the suspending rope, was at least equal to the height above the floor at which the wires were fastened. This method permitted the lamps to be lowered to the floor, and at the same time left no cable hanging in festoons about the building when the lamps were in their lighting position. From the terminal lamp of each circuit the wires were taken down the wooden pillars which supported the roof, through the floor, and (bracketed to the flooring joists) to the dynamo room. The incandescent circuits were arranged for a loss of potential of 10 volts. The installation was looked upon as being of a temporary character, consequently the electrical loss was considered to be of less moment than incurring a larger first outlay for heavier leads. Even with the above-named loss the leads

for a portion of the distance consisted of two cables, each containing 37/14s; and for the remainder of the distance to the point of distribution one cable of the same size was used. The distribution was effected by means of 7/16s cable, and finally by single wire. All cables were insulated to 150 megohms per mile.

The steam was generated in 12 multitubular boilers, the pressure being maintained at 120lb. per square inch. Three pairs of high-pressure engines were used, having cylinders 20in. in diameter, with a 40in. stroke. Normal speed, 80 revolutions per minute; and the total indicated horse-power with full working load was about 1,580. These engines were made in Melbourne, and were similar to those used for working the cable street tramways. I may say here that, recognising the very great importance of having the very best driving machinery, I urged the Exhibition Commissioners to send to England for engines specially constructed for electric light work. It was found, however, that time would not permit of this, and an order was given to a firm of local manufacturers who had engines partly made, and could guarantee, therefore, to have them ready in time. The countershaft was in one continuous line, and measured 202ft. 6in. over all. It was driven by ropes from the engine fly-wheels, in the face of each of which 13 grooves were formed for the reception of the ropes. The shaft was in three equal sections, one for each pair of engines. These sections were connected by movable clutches, so that they could run either separately or together, as required. To reduce to the lowest degree possible the inconvenience which would result if a pair of engines broke down, the dynamos driven by each section supplied current to lamps distributed over the whole buildings; so that if one-third of the light were taken off, no part of the Exhibition would be left in darkness. The main body of the shaft was 6¼in. in diameter, but the size was increased to 7½in. where the three-rope drums were fitted. The normal speed of the countershaft was 190 revolutions per minute. The dynamos were arranged in a double row on each side of the countershaft, the distances between the centre of the countershaft and spindles of dynamos being 28ft. and 33ft. respectively. At one end of the countershaft an automatic speed-recorder was placed. This recorder was essentially a chronograph, and consisted of a drum on which a sheet of paper could be fastened: the drum was driven by a tangent screw working in a worm wheel, which latter could be made fast to or released from the drum spindle by means of a friction clutch. The tangent screw was connected by a flexible coupling to the end of the countershaft. A small table was arranged, having a motion parallel to the drum axis. On the table an electro-magnet was fixed, the movable armature of which carried a small glass pen. The electro-magnet was put in circuit with a battery and clock having a minute contact. As the drum was mechanically driven (without slip) from the countershaft, its circumferential velocity was proportional to the speed of the shaft; and as the clock marked equal intervals of time on the paper, the distances between these marks gave the number of revolutions of the countershaft when measured on a suitable scale. The dimensions were adjusted so that the drum made one complete revolution in five minutes when the countershaft was running at the normal speed. Hence, if the speed were normal and without variation, the marks made by the clock would be in a straight line across the paper. If the speed did not vary, but was either greater or less than the normal, the clock marks would still be in straight lines, though making different angles with the edge of the sheet of paper. An irregular speed would show an irregular line. Geared from the same spindle that drove the reading drum, and mounted on the same base, was a small centrifugal governor. The opening or closing of the balls brought a small contact lever against either one or the other of two contact stops. Two incandescent lamps, one plain, the other coloured red, were hung over the engines, the position of the contact lever determining which, if either, of the lamps should be alight. At the normal speed neither would show light, but a variation of about half per cent. on either side would place one or other of the lamps in circuit. The majority of the diagrams taken by the recorder showed a gradual increase in the speed of the countershaft as the evening advanced. This fact will be referred to later on.

Generally speaking, the lighting throughout the term of the Exhibition was satisfactory. On three or four occasions only did anything occur which would lead the public to suspect that matters were not exactly as they should be. This comparative freedom from inconvenience through irregularities in the lighting was the result of the arrangement of the circuits rather than the constancy of supply to any one circuit.

The boilers, which were designed by a Victorian railway engineer, and built in Melbourne, behaved admirably, though working considerably beyond their proper capacity. The steam pressure was kept extremely regular, the maximum variation seldom exceeding two pounds per square inch for the whole evening's run. The fuel was coke, with a little coal added at times when difficulty was experienced in maintaining the full working pressure required. Notwithstanding the very regular steam pressure, the speed of the engines varied considerably, even though they were fitted with mechanism outwardly resembling Hartnel's automatic expansion gear. With the full load on the countershaft, and the engines indicating about 1,500 horse-power, a single dynamo thrown off or on produced a very sensible alteration in the speed of the rest of the machinery—sufficient, indeed, to necessitate the adjustment of the rheostat controlling the potential difference at the incandescence mains, and to show itself at the speed-indicating lamps. One evening some trials were made to ascertain the effect of an alteration in the steam pressure on the speed of the engines. For this purpose the pressure was altered one or two pounds every half-hour; and it was found that a variation in pressure of one pound per square inch produced an alteration in the speed of the engines of about a revolution per minute, all other conditions remaining the same. The cause of trouble was clearly enough in the governor, and I experienced a great deal of anxiety and annoyance from a fault which should not have existed. The fact is, the makers of the engines could not be made to understand the immense importance in electric lighting of absolute steadiness in the running of the engines, or that there was any difference in the driving of dynamo machines and street tramways.

The Brush Victoria dynamos ran very well through the whole six months the Exhibition was open. In the main they kept cool, though occasionally the thrust bearings showed an inclination to heat. The commutators ran with very little sparking when the brushes were properly adjusted.

Unfortunately, the above satisfactory remarks cannot be repeated with reference to the arc dynamos. In the first place, the insulation in many of them was defective or insufficient. Consequently, "electrical fireworks" formed a not unimportant part of the evening's proceedings, till such time as the faulty armatures and field coils had either been rewound or weeded out. In many cases, the machines ran for several weeks without giving any indications of weakness, when suddenly a breakdown in the insulation would take place. Another fault, more serious (if possible) than the last, existed in some of the armatures, namely, those which have been designated "thin-plate armatures." All the laminated armatures supplied, both thick and thin plate, were built up of the so-called H pieces, bound in with a strip of sheet iron, equal in width to the intended thickness of the bobbin core. There was no indication of the H pieces having been passed between rollers, or anything done to give them the same curvature as the armature. The horns of the H pieces were practically flat, hence their resistance to bending was simply that due to the thickness of the metal, which is insufficient in the case of the thin-plate armatures. A few weeks after the opening of the Exhibition several of the thin-plate armatures threw out plates. Two of these plates struck a door-post, and gave unmistakable evidence of the velocity with which they are thrown. On subsequent occasions the plates were not so neatly thrown out, but were caught by the field-magnets, and cut the insulation of the armature coils. By the time the Exhibition closed a goodly number of plates had been thrown out. To prevent accidents perforated zinc screens were placed over the armatures. The cause of these plates breaking off was evidently the continual bending to which they were subjected in passing through the different parts of the magnetic field in which they rotated. The force due to the rotation of the armature tends to bend the plates outwards, while that due to the attraction of the pole-pieces has the opposite tendency (at least with reference to the outer plates). Clearly, then, though the force due to rotation is constant, as the plates pass through a magnetic field which is not uniform in intensity or direction with reference to any given armature radius, the force tending to bend the plates inwards must vary in different parts of the field, and a constant bending of the plates must result. This mechanical fault was a very serious one, and might have caused damage to life and limb.

Before describing the methods used and tests made with the dynamo machines, it may not be out of place to give a few of the reasons which led to the selection of the method adopted. In order that the tests should be equally satisfactory to all concerned, it was essential that the machines should be tested under the actual working conditions, or while they were at work on their respective circuits. It was not thought to be important that all measurements taken should be of the highest degree of accuracy. As practical engineers know, the conditions of running do not remain constant (especially in arc machines) for many consecutive moments, and the fluctuations which take place affect all data, and the resulting efficiency from instant to instant. Hence the desire was to make tests which would be of practical rather than theoretical value. The many more recently suggested methods of testing dynamos in which all the measurements taken are electrical, such as Cardew's and Swinburne's, or in which the mechanical is the smaller part, such as Dr. Hopkinson's, were carefully considered with reference to the special form of machine to be tested. Of these methods, that of Captain Cardew seemed to be the only one that would give satisfactory results, for by it the machines can be tested under the actual conditions of working. Now that it is no longer thought that a dynamo is simply a generator of electricity,

Digitized by Google

and as such may be used indiscriminately for any purpose to which electricity is applied, makers designing special forms of machine to meet the different requirements for which they are to be used, the importance of considering the behaviour of the machine when working under the exact conditions for which it was designed cannot be over-estimated. In considering the matter, the many advantages, from a mathematical standpoint, of selecting one of the above-mentioned methods, or of running the machine on a closed metallic circuit, could not be overlooked. How much more satisfactory it would be to have the current almost absolutely steady, without those fluctuations caused by a faulty lamp or a bad carbon, which make the readings of the instrument used in testing so irregular and so difficult to obtain with any degree of accuracy! But the machines were not made to run on closed metallic circuit, and if they are to be tested fairly, must be tested with all the fluctuations of current, friction caused by pull of belt on bearings, and other modifying influences which exist under the normal condition of working. In some classes of machine, where the commutator has many segments, and each section of the armature winding has but few convolutions, especially if the machine is intended to light incandescent lamps or charge secondary batteries, the chances of error in any of the above methods would be a minimum. But with machines like the Brush arc dynamos, where the commutator segments are few, and the number of windings per armature coil very great, the errors introduced by running the machine on closed metallic circuit instead of the ordinary lamp circuit for which it was designed may be considerable, unless the metallic circuit is arranged to have the same self-induction as the lamp circuit. With such machines as the Brush the current should be maintained as nearly as possible at the value for which the machine was designed, as small alterations in the current may produce sensible alterations in the behaviour of the machine. The tests should be made when the machines have attained their state of steady temperature. It is, of course, needless to insist that the machine shall on each and every day reach its state of steady temperature, as the atmospheric temperature may vary considerably. It is sufficient if the machine attains a temperature which would be its steady state with some known atmospheric temperature within the range of practical work. If Dr. Hopkinson's method, where two similar machines have their armatures rigidly connected, were used, it would be needful to consider the exact relative angular position of the corresponding coils in the two armatures. If this were not attended to, the armatures might be so connected that the periodic fluctuations of the current would be either increased or diminished by the combination of the machines; hence the conditions of practical work might not be attained. In any case, with the two machines directly coupled (electrically), as suggested either by Hopkinson or Swinburne, the modifying effect of the self-induction of the circuit on the current fluctuation would be lost. For these and other reasons the elegant methods adopted by Hopkinson and Swinburne were deemed unsuitable in this particular case. Cardew's method was also rejected as being unwieldy, necessitating as it does the removal of the machines, and so many belt transmissions. As no other purely electrical method was thought of, it was determined to adopt the method involving the use of a mechanical dynamometer for measuring the energy absorbed by the machine, and to measure the output by the ordinary electrical method. The chief disadvantage of this plan appeared to be in the necessity of having all the instruments used accurately calibrated. The efficiency would not be the ratio of two sets of measurements taken by the same instrument, or even by two different sets of instruments which could be directly compared *inter se*. But as there is no great difficulty in the calibration of electrical instruments, at least within a degree of accuracy sufficient for all practical purposes, and the mechanical dynamometer can be directly tested, the increased facilities for testing the machines whilst actually working on their respective circuits was considered sufficient to outweigh the disadvantages of the method.

(To be continued.)

THE SHORT ELECTRIC RAILWAY SYSTEM.*

As the result of considerable work in elaborating his system, Mr. Short has finally succeeded in devising a complete arrangement for operating street railway cars, and the Brush Electric Company, of Cleveland, have undertaken the exploitation of the same through the Short Electric Railway Company, with a result that there are several roads in operation on the Short system, among them those at Columbus, O.; St. Louis, Mo.; Huntington, Va., and Ensign, W. Va. In a new catalogue issued by the Short Electric Railway Company, we gather some interesting details regarding their latest methods of construction and operation on both the parallel and the series system. The roads above-mentioned are all provided with overhead wires, and for this purpose the hangers are provided with clamps, which surround an insulator made of a mixture of hard rubber. Into this insulator there is screwed a pin with a long projection at its lower end, which is grooved at its lower end to receive the trolley wire. A steel clip passes over the trolley wire, and is riveted to the hanger. The clip is let into the trolley wire, which has an offset to receive it, with the result that the surface of the wire is left perfectly smooth for the trolley shoe which passes under it. A special brass connector is also used for joining up the ends of the wire. In order to insure perfect contact at all times between the wire and the trolley, the company have adopted a trolley shoe instead of the usual wheel, which presses upon the under surface of the wire and makes connection between the wire and the motor. The accompanying illustration shows the sliding contact. The trolley shoe is provided with a sole of soft material, which takes the wear, and is easily replaced at a cost of a few cents, and it is estimated that one of these wearing soles will run 1,000 miles without renewal. The spring bar is fixed to the top of the car by a universal joint, which allows the shoe to follow the trolley wire to a height of 22ft., and to a distance of 3ft. on either side of the track. It is claimed that by this method of construction and the application of the sliding shoe, the vibration of the trolley wire is obviated, and that on account of the wear on the shoe, the trolley wire itself remains entirely unaffected. Ordinarily each car is provided with two motors, which are protected from mud and dust by a covering for both sides and bottom. The arrangement is such that any part of the motor may be removed without disturbing any other part, and special care has been taken to avoid the destruction of the armature or magnet coils. An ingenious method of preventing the latter has been adopted, which consists in covering the magnet cores with copper, and also in surrounding the coils entirely with a copper jacket. By this means the extra current produced in the magnet coils on the sudden variation of the current strength is obviated. In order to avoid all noise, a special type of gearing has been adopted. The pinions which mesh with the gears are made of alternate layers of steel and a specially prepared material, which renders the gears strong and at the same time noiseless in operation. In the operation of the system two wires are run overhead, to which the cars are connected in series, the current being kept constant throughout.

Sliding Shoe employed in the Short System of Electric Traction.

The speed and direction of the cars are regulated by shifting the brushes around the commutator, which is performed from both platforms by a single movement of the controlling lever. Where a single overhead wire only is used, as in the parallel system, which is also operated by the Short Company, an additional resistance is placed under the platform of the car, which consists of a plunger of copper and conical-shaped hopper filled with coke or carbon. The plunger is connected with one side of the circuit and the hopper with the other. As the plunger enters the carbon, it decreases the resistance of the circuit until when it touches the bottom the full current is on. By pressing a foot lever the driver can cut off the current from the motor in an instant.

Besides these details of the car, the station arrangements have all been fully worked out, and, as noted above, the system has been in successful operation for some time past.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 2, 1889.

The Electric Situation in New York.—Involved and hopeless as the electric light situation in New York seemed last week, relief has already come. Judge Andrews, of the State Supreme Court, has rendered a decision continuing the injunction which restrains the city from interfering with the wires of the local companies, pending the trial of an action for a permanent injunction. Judge Andrews decides that the companies have a right to maintain their wires overhead until the subways for their accommodation are completed. He fixes the responsibility for the failure to complete the subways on the Subway Company, but intimates that the duty of keeping their wires properly insulated devolves on the plaintiffs, permission to repair old wires and to replace them with new and safe wires being obtainable from the Board of Electrical Control by a mandamus if refused. This decision, therefore, lets daylight in on the darkened situation, and strengthens the position of the companies as to their right to put their overhead conductors in good shape. The coroner's jury, which has been investigating the death of the lineman killed recently, has reported its inability to determine the origin of the fatal current, and recommends, among other things, that the insulation of the overhead wires be improved. It further recommends that a licensing board be appointed by some proper authority, and maintained by the various companies furnishing electricity, which shall grant permits only to men who have proved themselves competent to perform intelligently the duties of linemen. The result of this concurrent action has also been to fortify the local companies, and the result is that several of the new circuits have gone into operation. There is no doubt that the overhead circuits will be much more closely watched and regulated than they have been heretofore, and this in itself will be a great gain.

The National Electric Light Association on the Overhead Wire Question.—This agitation in New York has, of course, had a bad effect throughout the country, in so far as it has caused needless agitation and alarm on the subject of the danger of high-tension currents. In view of the check which might thus be given to the whole electrical business of the country, the executive committee of the National Electric Light Association has held a special meeting in this city during the past week, and has adopted a series of resolutions affirming the possibility of insulating satisfactorily currents of high tension, whether direct or alternating. These resolutions do not, of course, embody any new facts. They really constitute an appeal to the people, and are very much in the nature of a plank in a political platform. As a general thing, there is little need for such expressions of opinion, but as the public have lately been thrown into such a state of doubt and confusion and terror as to electric currents in general, it is well they should thus be made acquainted with the views of a representative body that has some right to be heard on the subject. These resolutions of the National Electric Light Association deal exclusively with the overhead wire question. The members of the Association recognise the fact that they will probably be required to operate more and more of their circuits underground, but the results so far obtained with underground methods have been so unsatisfactory that they do not feel called upon to express even a qualified opinion on such systems.

Mr. Edison on the Overhead Wire Question.—Another utterance on this subject is that from Mr. Edison which finds a place in the November number of the *North American Review*. Mr. Edison there expresses his convictions as to the impropriety of operating high-tension currents, either overhead or underground, while as to alternating currents, he says frankly that if he had his way he would prohibit their use altogether, on account of their deadliness. In connection with this subject, Mr. Edison mentions that when the Edison Company purchased the Zipernowsky-Deri patents for this country, they did so against his protest, and that his views are stated in full on the company's minute book. While according to Mr. Edison the respect that is due to his position, and granting the entire sincerity of his utterances, there are a great many electricians in this country who regret that he should take such a stand. It is impossible now that any man, or body of men, should resist the course of alternating-current development. Joshua may command the sun to stand still, but Mr. Edison is not Joshua.

Electrical Articles in the Magazines.—While mentioning the *North American Review*, I may add that the number this month is a very striking exemplification of the great interest taken by our periodicals in electrical questions generally. In addition to the article by Mr. Edison, there is one by the right honourable gentleman who has been buying Westinghouse apparatus in an underhand way for sale to the State for purposes of electrical execution. A third article of electrical interest in the *North American Review* is that by Dr. Norvin Green, the president of the Western Union Telegraph Company on the question of "Are telegraph rates too high?" Dr. Green says they are not. The accusation that the stock of the Western Union Company is watered he meets squarely by asserting that within the last 24 years the Western Union Company, has spent more than $25,000,000 of its cash earnings and the proceeds of $6,350,000 of bonds in the construction and extension of its lines and the purchase of other telegraph properties, and that during the same period $28,400,000 of its capital stock has been paid for various telegraph systems it has absorbed. The capitalisation as it now stands is not above the cost value of the company's properties, while it has been admitted that the contracts of the company are of greater value than its properties. As to the cost of telegraphing, Dr. Green says, after pointing out how large the mileage is, "To expect this vast system, covering an area of 3,000,000 of square miles, in great part over rough and sparsely settled territory, to be maintained and operated (at a cost for operators and linemen of more than double the rate of salaries paid in any country in Europe) at the same rate of tolls, without regard to territory, that are paid in the smaller countries of Europe is unreasonable and unjust."

The Government Suit Against the American Bell Telephone Company.—It was expected that when a change in the political control of the country came, and President Harrison succeeded President Cleveland, there would be a relaxation of the efforts on the part of the Government to push the suit against the American Bell Telephone Company for obtaining its patents by fraud. Attorney-General Miller, of the present Administration, is quoted, however, as having said that the Government is determined to press to a speedy conclusion, and with all the forces at command, this extraordinary case. It is stated that the work of specially pushing the prosecution has been entrusted to an official to whom has been given full power to use every legal means in urging the suit as fast as possible. The reason for this action on the part of the department of justice it is not very easy to see, and it is very certain that if such be the determination, the Bell Company will resist this unusual kind of onslaught with all the means at their command, even although they have thorough confidence in the strength and righteousness of their cause. The litigation is an interesting one for the public, because everybody sees that a huge prize is at stake, and nearly every telephone subscriber has a dim sort of idea that if the Bell Company were worsted he would get his telephone service somewhat cheaper.

The Study of Electrical Engineering.—The various schools and colleges are paying more attention than ever to the study of electrical engineering, and the reports from all quarters go to show how great is the interest in the subject in educational circles. Columbia College in this city has just begun its new electrical engineering course, and starts with several students. It is the intention of the college to grant the degree of Electrical Engineer for this post-graduate course, which extends over two years, and is devoted solely to electricity; while for the partial course of one year, a simple certificate will be given. Reports from Cornell show that at that seat of learning the subject of electrical engineering is in greater favour than ever. Three years ago the number of students taking up the electrical course in Sibley College, at Cornell, was 59. The total number

Digitized by Google

in this college at the present time is no fewer than 166. If this sort of thing goes on we shall soon have to start an electrical college. It is quite significant that electricity should be the chosen study of so many men at this time, when the many consolidations among the leading companies have tended to throw a good deal of talent on the market, and it shows how thorough is the belief as to the future of electricity and the great opportunities it will afford to qualified men. In point of fact, while there are plenty of men in electrical work in this country to-day, the number of those who have been thoroughly educated for their duties is much too small. There is a superstition here that a college-bred man is apt to be a very useless kind of a creature, but there is a growing perception of the fact that the man who is theoretical as well as practical has, at east, a little the best of it.

Continuous Currents from Alternating Currents. — The problem of obtaining continuous currents from alternating is one that has received not a little attention, and various solutions have been offered on both sides of the Atlantic. Mr. Nikola Tesla has applied himself to the matter, and now offers a simple and ingenious solution. His idea and method consist broadly in directing the waves of an alternating current so as to produce continuous currents by developing in the branches of an alternating-current circuit certain manifestations of energy or active opposite resistances by which the alternating-current waves of opposite sign are diverted through different circuits. Thus the currents of different sign are, so to speak, sifted out: those of one sign passing over one branch, and those of an opposite sign over the other. There may thus be obtained from an alternating current two or more direct currents without the employment of a commutator. Mr. Tesla proposes both electrical and electro-magnetic methods for achieving this result. In the electrical method the device to create an electromotive force counter to the waves of current on one side may, for example, be batteries or continuous-current machines. In the electro-magnetic method, instead of producing the electromotive force in each branch of the circuit, a field of force may be established, and the branches be led through it in such a manner that an active opposition will be developed therein by the passage, or tendency to pass, of the alternations of current. Another purely magnetic method is that wherein Mr. Tesla employs two strong permanent magnets, the armatures of which are built up of thin laminæ of soft iron or steel, the amount of magnetic metal which they contain being so calculated that they will be nearly or fully saturated by the magnets.

The Regulation of Accumulators in Electric Lighting.—At the meeting of the American Institute of Electrical Engineers this week, Mr. G. B. Prescott, jun., the electrician of the Electrical Accumulator Company, read a very able and interesting Paper "On Methods of Regulating Accumulators in Electric Lighting." Mr. Prescott pointed out in his Paper that the modern electrical accumulator was a thoroughly trustworthy piece of apparatus, and that it could be made to play a very important part in supplementing the present methods in use for electric lighting, relieving stations and isolated plants of the necessity of operating continuously throughout the day at a time when the loads would be lightest and the expense correspondingly high. He illustrated and explained methods of applying the accumulator as an adjunct to the two-wire and three-wire systems, and went on to show how counter E.M.F. cells could also be used to replace the present dead resistance pressure equalisers. He dealt also with the arrangement of locating one or more series of cells in sub-stations conveniently placed near centres of current consumption, and brought out very forcibly the various advantages secured from a scientific and systematic manner of employing the cells so as to get out of any plant its full efficiency while it is in actual operation. Some of the methods described by Mr. Prescott are remarkably ingenious, and it would be interesting to know whether they are not merely theoretical, not having yet reached the stage of practical demonstration.

Storage Battery Patent Litigation.—I may mention, by the way, that the Electrical Accumulator Company, whose cells, of course, are alone referred to, has just succeeded in obtaining an injunction against the Fourth Avenue Railroad in this city, which has been using the Julien cell on its storage battery cars. The cells in use having been made under the methods limited to the Electrical Accumulator Company, the judge has granted an injunction preventing the Julien Company from using cells in which the active material has in any way been applied to the plates in the form of a "paint, paste, or cement." The Julien Company have, perforce, been obliged to suspend the running of their cars, which have won no small amount of popular favour. They are now understood to be actively engaged in manufacturing plates in which the active material is applied in the form of powder, and submitted to tremendous pressure. As soon as these plates are ready the cars will be put in operation again.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *November* 9, 1889.

During the recent visit to the Castle of Fredensborg of the King and Queen of Denmark a temporary installation of electric light had been arranged at the Castle by Prof. Jurgensen's electrical establishment, Copenhagen. It only comprised the large dome apartment, which was used as a dining room, and where 80 incandescent lamps have been fixed. The effect was very good, and a capital photograph was taken one night of the royal party at dinner.

The firm of Luth and Rosen (Elektriska Bureau), Stockholm, have just about completed the largest private electric light installation in Sweden, viz., at the large woollen works, Malmö. At the Malmö establishment there are 1,735 incandescent lamps of 16 candle-power each, and 8 arc lamps of 800 candle-power each. In the branch establishment at Turnlund are 115 incandescent lamps (16 candle-power) and two arc lamps (800 candle-power). These two installations comprise four dynamos, which require somewhere about 200 horse-power. In order to make gas entirely superfluous, there is a battery of accumulators of 55 elements. Mr. G. Bellander is the engineer for this installation.

The courtyard of the Royal Castle at Stockholm has been lighted by electricity. An arc lamp of 1,400 candle-power has been placed over each of the four gates. The lamps have been delivered by the well-known firm of J. E. Erikson, and the electricity is supplied from the Stockholm Electric Light Company.

In Christiania the question of an electric tramway appears to be advancing. Some gentlemen have been inspecting similar concerns in various countries, and their report is to the effect that electric tramways are both the safest and the cheapest. The result of this favourable report is a considerable enlargement of the original scheme. Also in Stockholm an electric tramway has been under discussion in connection with the projected Exhibition in the year 1892. The site for the Exhibition is some way outside the town, and an electric tramway will probably be erected between these two points.

The question of a large electric central station in Stockholm is apparently advancing, the directors of the Stockholm Gas Works having just applied to the Corporation for 500,000kr., so as to enable them to commence work on the central station, which, when completed, is expected to cost about 1,500,000kr., or rather more than £80,000. The question has been on the *tapis* for some two or three years, and the gas works have once or twice previously submitted proposals to the Corporation for the erection of a central electric station. As soon as the above sum of 500,000kr. has been voted, applications for electric light will be at once invited, which, of course, will serve as a guidance with reference to some of the details of the plan. Electric light is already in somewhat extensive use in Stockholm, there being about 15,000 incandescent lamps, which is about 10 per cent. of the total number of gas flames. Of arc lamps there are about 300, and since 1886 the use of electric light in Stockholm has been doubled. The whole of this light is supplied from comparatively small installations. The gas company is of opinion that if the electric light could be made available for the whole of Stockholm, about 24,000 lamps would be required. If the area were confined to the portion of the town called Nether Norrmalur only, some 13,000 lamps would probably be wanted: this is the handiest district for a central station, a large amount of light being required in it. Nor will there be any difficulties in extending the area, should other portions of the town be desirous of obtaining electric light. It is proposed to charge 4½ öre, or three-fifths of a penny, per hour per 16-candle lamp, with reduction for larger consumers. It may be added as a somewhat curious incident, that the gas works in the same communication to the Corporation, in which they ask for 500,000kr. towards an

Digitized by Google

electric central station, also ask for a similar sum as first instalment towards the erection of new gas works, which, when completed, are calculated to cost 4,956,000kr., or some £275,000.

The large and enterprising General Telephone Company at Stockholm is about to introduce a new arrangement, which will no doubt tend to further increase their already large number of subscribers. The company intends to start a separate class of cheap subscribers, who can have a telephone for an annual subscription of no more than 50kr., or £2. 15s. 6d. These telephones are intended for families and business people in a small way, and the number of conversations is limited to 35 per week. Special arrangements will have to be made at the station for the serving of these cheap subscribers, who will not be served so quickly as ordinary subscribers, and so as to avoid misunderstandings, the names of the former will be printed with a special type in the company's catalogue.

At Drontheim, Norway, a Mr. Schreiber has obtained concession for the erection of an electric central station. There appear to be a good many applications for electric light already. The Frognerkilen Engineering Company, Norway, will supply the machinery, &c.

In Denmark the telephone has come into very general use in a number of rural districts, villages, and small towns; altogether in places where there is not much likelihood of meeting with telephones in England. A number of fishing villages and lifeboat stations have thus been connected, which has proved a great boon. As an example of a small town with exceptional telephonic connection, may be mentioned Lemvig, in Jutland. There are two State telephone lines to two fishing villages, Harboöre and Fjaltring, a salvage telephone line connecting the town with all the lifeboat stations on the west coast of Jutland between Thyborön and Nymindegab, and in addition the town is in telephonic connection with most of the towns in middle Jutland.

The large Houstholm electric lighthouse on the west coast of Jutland was opened a few weeks ago, and has so far worked in the most satisfactory manner. The height of the lighthouse is rather more than 200ft., and the power of the electric light is some 2,000,000 Borcel-light. The magneto-electric machines, of which there are two—the twin principle having been adopted wherever possible—are from the De Meritens' establishment in Paris, and have a capacity of 45 volts and 250 amperes. The lensal arrangement is from Barbier and Co., Paris; its diameter is 182 metres, and the height about three metres. It is divided into thirty sections, and the lamps are self-regulating, and so arranged that they can be changed almost simultaneously. As a reserve there is a powerful paraffin lamp. The lighthouse gives three short flashes every ten seconds. The electric light is also used for lighting the various buildings belonging to the lighthouse, and electricity is used for working the two powerful sirens, which, although at some distance, are connected with the lighthouse.

CORRESPONDENCE.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The discordant note sounded by your correspondent "Telegraphy," amidst the harmony of the recent social gathering, is heard now not for the first time; and as it appears to have awakened some sympathising echoes in your editorial columns, it demands the more serious attention.

Whatever may be said as regards some of the statements in your correspondent's letter, it seems to me that the general drift of his remarks is based upon a misconception, which lies at the root of the whole matter. I refer to the suggestion that the Society of Telegraph Engineers, under its new title and present development, has deviated from the objects of its foundation, and that foreign interests have shouldered the legitimate owners out of their inheritance.

Such a suggestion is at variance with the record of the intentions of the founders, as laid down in the original statutes of 1872, which stands as follows:—

"The Society of Telegraph Engineers is established for the general advancement of electrical and telegraphic science, and more particularly for facilitating the exchange of information and ideas among its members."

It is a significant fact, and one which should not be overlooked, that in stating the objects of their society, its founders placed *the advancement of electrical science* in the front rank. It was an obvious conclusion at that date to couple the word "*telegraphic*" with electrical science, and that a society of practical electricians should adopt the title by which all engineers who then practised electricity called themselves, viz., "telegraph engineers."

But that the telegraph engineers of 1872 had not chosen their profession, intending to confine their attention solely to the practice of telegraphy, is abundantly proved by the sequel. It is only necessary to refer to the list of the first Council of the Society and the roll of original members to realise the fact that the telegraph engineers of 1872 are the electrical engineers of to-day. Here will be found the names of many men, some still with us, and others now passed away, who, then well known in connection with telegraphy, have since been foremost in the development of electric lighting and other branches of electrical engineering. The great manufacturing firms and companies, some of whom even still bear titles specially identifying them with telegraphy, in earlier days devoted their chief attention to the making and laying of telegraph cables. But these same firms have in recent years added electric lighting departments to their business, and now manufacture electrical appliances of all descriptions.

The new title of "Institution of Electrical Engineers" is merely a recognition of the fact, that under the modern developments of electrical science the same objects as were present in the minds of the founders of the Society are not now adequately represented by the title which was formerly appropriate.

For the same reason it would not be adequately carrying out those objects, if a preponderance were given to telegraphy, either in the subjects chosen for discussion, or in the election of members of the Council.

With respect to the former, I am not aware that any complaint has been made that Papers on telegraphy offered for reading at the Society's meetings have been rejected. As regards representation on the Council, if those who are specially connected with telegraphy think they do not obtain their fair share, it would be easy for them to combine in recommending certain candidates to the Council for the next election. This course was, if I remember rightly, suggested by certain speakers on the Council at the discussion which took place on the election day last year, and, if adopted, would no doubt receive proper attention.

Your correspondent concludes his letter with a threat of schism: that he and his *confrères* will withdraw and form a society of their own. I sincerely hope that nothing of the kind will be done. If it is, I am sure telegraphy will suffer by thus lopping itself off from the common stem. The formation of a separate Institution of Mechanical Engineers may, perhaps, be quoted as a precedent and justification for such a course; but any such analogy would be fallacious. A mechanical engineer need not necessarily be very familiar with the other branches of engineering, while with the present case it is wholly different. Electrical science is one, and all its branches are absolutely dependent upon it. The man who desires to be in the front rank in telegraphy must be first of all an electrician. He must keep in touch with the general development of electrical knowledge, or he will be distanced in his own art by men of wider views.

The remedy which may perhaps meet the objects of your correspondent, so far as they appear to be to any extent legitimate, seems to me to lie in another direction. Let all work together to increase the material prosperity of the Institution of Electrical Engineers, and endeavour to hasten the day when they may leave the hospitable roof which has lodged them hitherto, and build suitable premises of their own. It would then be possible to have more frequent meetings, and there might be separate sections, with their own committees, to give special attention to telegraphy and any separate departments which might be found desirable.

By this means, while every separate interest would receive its full share of attention, the unity would be preserved of an institution which has before it a future of inestimable importance.—I am, Sir, &c.,

OBSERVER.

THE OPERATIVE ELECTRICIANS' UNION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: However much you may be personally adverse to the recently-established Amalgamated Union of Electrical Opera-

Digitized by Google

tives, I am sure that you will give publicity to this letter, and so accord fair play to a class of men of whom I think you have gone out of your way to speak in tones of contempt. If your representative had given a faithfully-recorded report of what fell from the lips of the speakers you would scarcely have stated that the objects of the meeting were shrouded in vague uncertainty. The Rules of the Union are in course of formation, and when they are finished I can promise, as Chairman of the Sub-Committee appointed to draw them up, that you shall receive a copy immediately. Do you consider the industry an important one or not? If you reply in the affirmative, I would ask if you suppose that the operatives are not as well qualified to estimate the status of their occupation as yourselves? They think that they are, and as a natural sequence set to work to do what every industry of any magnitude at all has done long ago, viz., establish a Trade Union for the protection of their interests. Do not be harsh and cynical, Mr. Editor. Do not regard us as foes until we have evinced some hostility. I can assure the employers, through you, that with the exception of one firm, the men are thoroughly satisfied with the treatment they are receiving from their masters, and all round I meet with unstinted expressions of perfect good-will and contentment. Of course, I except the one firm I have referred to, which shall be nameless; but I will state, *en passant*, that, considering the high position it holds in this industry, I am astonished at hearing such grave charges against it. Our desire is to preserve the quietude of which I have spoken, to band together competent workmen of every branch in the trade, and to ensure for them fair and just wages. The time has long gone by to scoff at the idea of unionism. It has become a necessity and a duty. By our laws no incompetent workman will be eligible for membership, and that, I assume, will be nothing detrimental to the interests of the employer.

I do not presume to give advice to you, Sir, but I venture to suggest that your duty is to endeavour to promote harmony and concord between wage-earner and wage-payer. Dissension germinates spontaneously enough, Heaven knows, without being fostered by extraneous irrigation. You might retaliate by saying, "Why get assistance from extraneous sources—Mr. James Rowlands, M.P., to wit?" No charge of interested selfishness and intentional agitation was ever more groundless than the one made by you against that gentleman. He had no knowledge whatever of the scheme afoot until four days before the meeting of October 26th, at the Albion Hall. The committee had not fixed upon anyone to address the meeting, and I suggested that a labour M.P. should be asked to do so. Mr. Rowlands being member for the next division to that in which the meeting was held, he was singularly acceptable; and no one who heard his speech could have found the slightest flaw in its impartiality and freedom from bias. He is one of the men, Mr. Editor, of whom working men are proud. He belongs to our class, and it is to him and such as him that the elevated position the working classes occupy to-day is due. When you insinuate that the workman is an easily-led creature on account of insufficiently developed powers of discrimination, you are throwing stones in a glass house, assuming that you are writing in the interests of the employers. Were George Stephenson or the late Sir Daniel Gooch, and are Mr. Preece and Mr. Paxman included in your category? Do not blame us, Sir, until we do that which is wrong.—Yours, &c.,

THE CHAIRMAN OF THE MEETING ON OCT. 26, 1889.

November 9, 1889.

THE THEORY OF ACCUMULATORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: At the present time the lead accumulator is the subject of much discussion both in practical and theoretical circles. Everybody who is acquainted with the subject feels that neither has the lead-accumulator reached practical perfection, nor has its working received a proper theoretical explanation. The researches of Ritter, Planté, Faure, Gladstone and Tribe, Fitzgerald, Frankland, and many others, have all been in the same direction, and under the belief that the sulphuric acid in the lead-accumulator is the important thing, there being formed certain kinds of "lead sulphates." But it is already proved that the only chemically-known sulphate of lead is not at all the body which ought to be present in the electrodes of a lead accumulator. The fact that during the charging the specific gravity of the sulphuric acid increases, and decreases during the discharging, has led to the opinion that the active material of the plates absorbs and binds a certain quantity of sulphuric acid during the discharging period. Different people have found different quantities of absorbed sulphuric acid. The sulphuric acid, it was considered, should always be the "electrolyte." Also the lead sulphate itself was considered to be the electrolyte, though it is nearly insoluble in the liquid of the cell and present only in a very small proportion. Some time ago I found that acids other than sulphuric acid will perform the requisite functions in a lead accumulator as well: for example, phosphoric acid. I was also struck by the analogy in charging a palladium accumulator and a lead accumulator. The negative plate in each case takes up hydrogen till the point of saturation is reached. Charged over this point there is still an absorption of hydrogen; but this gas is not kept as good as before, and escapes easier. Such a charged plate (it may be charged in any acid which does not dissolve the material of the plate, or which is not acted upon by the electrolytic hydrogen) is like a zinc-plate, giving an electric current in nearly all solutions used up to now for similar purposes. Of course there must be placed in the electrolytic vessel also a plate or a body for purposes of depolarisation, such as the highly oxydised compounds of lead, manganese, nickel, cobalt. With a diaphragm also liquids like nitric acid, chromic acid, chloride of iron, &c., may be used for depolarisation.

It would seem from these experiments that the charged material of the negative plates in a lead accumulator probably consists of a kind of *amalgam of lead and hydrogen*. With this theory all the troubles of the sulphate-theory disappears. We now see why only a seventh of the "active material" is used for storing the current; why all different systems of accumulators give nearly the same capacity; why the E.M.F. is constantly increasing in charging, and decreasing during discharging; why the specific gravity of the dilute sulphuric acid is altered. The chemistry of the lead accumulator becomes more simple and logical. During charging a certain quantity of water is decomposed, the hydrogen being absorbed by the spongy lead and the oxygen being bound by the lead-oxides, in changing these into a higher oxidised form. (M. Wernike was the first to make researches about this so-called peroxide of lead, and M. Bandsept has called attention to the fact that we know nothing certain about the compounds in the lead accumulators.) The specific gravity of the acid must increase in taking away the water from the solution. During the discharge, water is again formed, the hydrogen of the negative plates combining with oxygen from the highly oxidised positive plate: this water will decrease the specific-gravity of the sulphuric acid. The fact that the resistance of a cell will be altered is clear, because during the discharge the plates would contain at least pure water, if some diffusion had not taken place; and the very important transmission of the ions in the electrolytic fluid would not facilitate the diffusion. A charged negative plate taken out of the protecting dilute acid into the open air soon becomes hot, the hydrogen burning to water with the oxygen of the surrounding air. If this negative plate is again placed in the electrolyte, practically no current will be obtained. (Of course, also, the lead in its very fine divided form will easily take up oxygen, and all the easier since the plate has already got hot by the previous burning of the hydrogen.)

The researches which should be made about accumulators in future should give account of the properties and the proper ways of obtaining *the different amalgams of hydrogen*. It is quite certain that lead is not the only metal which will form hydrogen amalgams. Mercury will do it, also iron; nickel and other metals, which would not give compounds with hydrogen by the ordinary chemical way, would do it electrochemically. The opinion of Dr. Bell in his article about the use of accumulators for the electric propulsion of tram cars (*Electri-*

Digitized by Google

cian, October 18th, p. 609) is also my own—that the accumulator will be an important apparatus in the future, but that the present accumulator must be improved till it is suitable for general practical use.—Yours, &c., PAUL SCHOOP.

BADT'S HANDBOOK OF INCANDESCENT WIRING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There appears to me to be a serious mistake in the handbook of incandescent wiring by F. B. Badt, a review of which appeared in your number of October 11th.

Rule VII., Chapter XXVII. (p. 49), stands thus:—"Where lamps or groups of lamps are placed at different distances from the dynamo, determine first the proper wire for each lamp or group of lamps if placed on independent circuits starting from the dynamo, then combine all wires running in the same direction."

The size of wire is calculated by Rule VI., a certain loss being assumed in the leads. This rule will, I believe, give incorrect results.

The total loss will always be less than that assumed, while the drop of potential in the leads will be less for the nearer groups and greater for the further groups than that calculated from the assumed loss of power. The first-mentioned error is of little importance, being on the right side, but the second may lead to serious mistakes in calculating the sizes of wires required for distant groups of lamps.

The reason for this may be easily seen if we consider the fall of potential along the different circuits. Let us first suppose that the circuits are all kept separate from each other. Then the fall of potential will be uniform along each pair of leads, and since the total fall is the same, therefore the rate of fall will be different for each pair. If the leads be now joined at the first group of lamps the difference of potential between them formerly existing can no longer continue, and a redistribution of the current in the leads will take place. The result of this will be that the total fall of potential at the first group of lamps will be less than before, but the fall up to this point in the leads for the further groups of lamps will be greater than it was before.

By way of illustration, I have calculated the fall of potential along the leads in the example given on p. 50 to Rule VII. The results are given below:—

	Up to the 1° group of lamps.	Up to the 2° group of lamps.	Up to the 3° group of lamps.
Resistance of leads, ohms.	·0332	·058	·0663
Current, amperes	75·58	49·83	24·72
Drop of volts	2·509	5·4	7·04
Power spent, watts.....	189·6	144·	40·5

Total loss of power is 374 watts instead of 437, which is 5 per cent. on whole power of dynamo. The drop of potential varies from 2·5 to 7, instead of being 5·8, which is 5 per cent. on the total E.M.F. (taken as 115·8) of the dynamo.

In many cases, as will be easily seen, the errors may be much greater than those in this example.—Yours, &c.,

C. FREWEN JENKIN.

Wistaston Manor, Crewe, November 12, 1889.

LEGAL INTELLIGENCE.

Maxim-Weston Electric Company v. Watt.

A motion in this action came on for hearing on Friday before Mr. Justice North, the object being to compel further and better answers from the defendant to certain interrogatories administered by the plaintiffs, having reference to the alleged dealings in the Company's shares by Mr. Watt, and to his having made profits thereby unknown to his co-directors, also to an allegation that he had expended the Company's money and employed the Company's servants and machinery in making experiments with regard to certain patents of which he was the owner, and that he ought to account for the money so expended. The defendant had declined to answer certain interrogatories on the ground that they were immaterial and irrelevant. The motion was argued by Mr. Cozens-Hardy for the liquidator of the Company, and by Mr. Higgins and Mr. Hart for the defendant. In the result, his lordship ordered the defendant to answer four of the interrogatories, but not two others, which, he thought, went further than the plaintiffs were entitled to at the present stage of the proceedings.

The trial of the action to be postponed until ten days after the answers are put in.

United Telephone Company v. Mitchell.

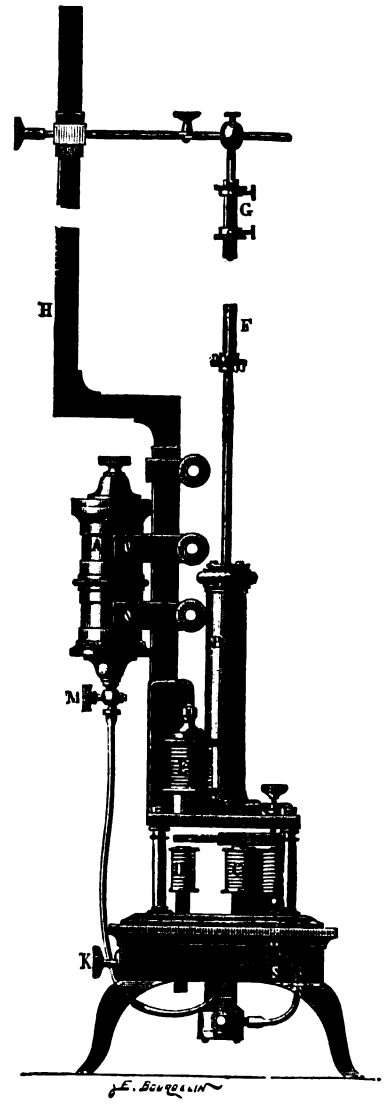
This action came before Mr. Justice Chitty, in the Chancery Division, on Saturday last, on motion for judgment in default of defence.

Mr. MICKLEM stated that the defendant had put in no pleadings. Particulars of breaches of patent had been delivered by the plaintiffs, containing the charges against the defendant. A draft order had now been prepared, which the Court was asked to adopt, in the form made in previous cases of a similar character. Costs, charges, and expenses were asked against the defendant in the matter.

Order accordingly as asked by plantiffs.

THE LACASSAGNE-THIERS ARC LAMP.*

The Lacassagne-Thiers arc lamp was patented in the year 1855, and its interest is therefore mainly historical. Its description is worth giving, however, if only because it works on a principle different to that of other arc lamps, and because it contains a feature since universally adopted, namely, an electro-magnet wound with a high-resistance wire, and placed as a shunt upon the arc.



Referring to the accompanying figure, A is an iron vessel containing mercury; B, an iron cylinder; C, a thick wire electro-magnet; D, a fine wire electro-magnet arranged as a shunt upon the arc; E, a fine wire coil, placed in series with D to increase its resistance; F, the movable negative carbon-holder; G, the positive fixed carbon-holder; H a rod, carrying the cross-piece belonging

* Translated from M. Hippolyte Fontaine's "Éclairage à l'Electricité," by kind permission of the Author.

Digitized by Google

to the positive carbon-holder, and to which the vessel A is attached. M is a cock to which is connected an india-rubber tube terminating in a valve which allows the mercury to penetrate into the cylinder B; K is a screw by which the height of the electro-magnet D can be regulated; S is a tap by means of which the cylinder B can be emptied.

A bar of iron supported on a knife-edge above the electro-magnets C and D oscillates from one side to the other according as the attractive force of one or the other of the magnets preponderates. These oscillations actuate the communication valve: when C preponderates this valve is shut; when D preponderates the valve is open, and the mercury flows into the cylinder, and the piston is forced up. After the lamp has been burning for four hours it is necessary to fill the mercury reservoir and renew the carbons.

The author has seen one of these lamps worked off a battery, and he can assert that no modern lamp gives a steadier arc. Its mechanism is so sensitive that the armature, instead of oscillating, immediately takes up a nearly fixed position, which it maintains until the carbons are consumed, allowing a thin stream of mercury to flow steadily into the cylinder.

Although the Lacassagne-Thier arc lamp has been used in numerous projection experiments both at Paris and Lyons, it has never come into commercial use.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

October 22, 1889.

16,652. W. SHAPLEIGH. London. Improvements in the moulds for casting the plates of secondary or storage batteries.

16,630. E. J. CHAMBERS. London. Improvements in attaching or fastening telpher cables and electric-light cables, telegraph wires, telephone wires, and other cables, wires, and rods to insulators.

COMPANIES' MEETINGS & REPORTS.

The Western and Brazilian Telegraph Company (Limited).

The eighteenth ordinary general meeting of the Western and Brazilian Telegraph Company (Limited), was held at Winchester House, 50, Old Broad-street, on Thursday, November 14, 1889, under the presidency of W. S. Andrews, Esq.

The SECRETARY (Mr. R. M. Cunningham) read the notice convening the meeting, and the minutes of the last meeting, which were confirmed by the present meeting, and signed as correct. The report of the Directors was taken as read.

The CHAIRMAN then addressed the meeting at length, and, in the course of his observations, said: Gentlemen, to-day my task is not quite so satisfactory as it has been on several occasions, because I have a matter to deal with of some considerable importance, and one which is not of an agreeable kind. As we have to deal with the matter at some length, I do not propose to go very fully into the accounts, because they are relatively, under such circumstances, unimportant; and I will, therefore, just touch upon them shortly, and come as quickly as I can to what, no doubt, you are much more anxious to hear about. Now, you will notice that practically the outcome is pretty much what it was at the corresponding period of the previous year. The circumstances, however, are not the same. The first part of the half-year showed a considerable increase of traffic; the last part of the half-year shows a considerable decrease—partly owing to the reduced rates, and partly owing to the interruptions that were sustained by the cables. The difference, however, at the end of the six months only amounts, I think, to some £318. The expenses of the half-year were considerably increased. The item of the London expenses under "C" in the report is practically the same. There are one or two very small increases to deserving clerks, who received a little more pay owing to their greater length of service; but the expenses under "B" for ships and cable are larger—the cable by £2,148, and in the case of the ships the increase is £1,305. That arises in this way: the "Norseman," the Company's vessel, had to be ordered home for new boilers, and it was too dangerous, in our opinion, to leave the service without protection, and we therefore hired and chartered another ship (a 12-knot ship), upon very moderate terms, to take the place of the "Norseman." The "Norseman," therefore, only appeared in the accounts for some three months, and there is a considerable saving —some £2,228—but that is more than balanced by the increased expenses on account of the hired ship, the "Buccaneer," and the total difference, therefore, under abstract "B," is some £2,000 odd. Then we come to Abstract "A," where there is an increase. That arises from an increase in the premiums on the currency. In so far as it arises from that, in the net result it means a great gain, because we, of course, receive a great deal more from the collection than we pay in increased premium; and there is a large balance in our favour under that head. The increase on the coast, and in this abstract "A," is partly occasioned by the prevalence of fever there. The clerks had to be shifted a great deal. One or two of the stations had to be shifted, and we had to provide temporary accommodation. The consequence was that there was an increase of £185 in miscellaneous expenses, £213 in rent and taxes, £215 in travelling expenses, and £257 in medical expenses. I think that comprises all the items that were increased by that cause except salaries and wages, where there is an increase of £925, because we were telegraphed to from our stations abroad to send increased help owing to the need of assistance, and we had necessarily to do so or the system would have been stopped. The items of stores and instruments shows an increase of £700, which means that we have had to increase the things there, and that is not a recurring item. Therefore with respect to many of these items I do not think you will be troubled again—at all events not in the shape of increases. I do not know that there is anything more to say with respect to that part of the business, except that the balance enables us to recommend you to declare a dividend at the rate of 4 per cent., after putting the usual sum to reserve, and to debenture redemption, and carrying over a satisfactory balance. Well, now, gentlemen, I have to deal with the subject of the loop lines, and in connection with that you know that we have always suffered, almost ever since we have been a Company—although we have not suffered from it so materially as we might—from the competition of the Brazilian Government, which has existed, as you know, for many years. Our report will have prepared you for the statement I am now about to make, because we show you there an interchange of certain telegrams, and a decision by the Brazilian Government that we are not to be allowed to lay there loops which you have approved of our laying, and which we conceived to be in the best interests of the service. We do not, of course, pretend to say that we cannot maintain our lines without these loops, because we have always hitherto had to do so; but we do say that if we are allowed to lay them—and we believe we are entitled to lay them—your service will be conducted in the most perfect and efficient way it can be, and we think that that is the way a telegraph service ought to be conducted. Now, the origin of this concern, and of the concessions, dates as far back as 1873. At that time the empire of Brazil was isolated from all telegraphic communication with the rest of the world; her commerce was sustaining a necessary disadvantage, which was sure to accrue from such a state of things; her politics had to be conducted without the assistance of immediate international communication, and her ports were severed from one another; and generally her position was one which a great empire no doubt thought to be practically intolerable. Therefore, at this period of 1873, it was proposed that a concession should be given to establish communication between

Digitized by Google

Brasil and Europe. That concession was opposed at that time by the Director-General of Brazilian Telegraphs, and I may say that the same gentleman is still the Director-General. He appears to have thought that although there were great obstacles to the erection of telegraphs throughout the Empire—namely, that in large districts there were no roads, there were extensive forests, swamps, and rivers—still he thought, I take it, that ultimately he would be able to establish the necessary lines for the accommodation of the Government; but as against that a good many people no doubt saw that that was a work of years. They saw, too, that British capitalists would not invest their money to lay a cable between this country and Brazil unless they could immediately get traffic for it. In the state of the communication at that time no traffic could have been coming forward, and consequently the form that the concession first took was this—that one Company should lay the whole line, not only the line from this country to Pernambuco in Brazil, but also between Pernambuco and all the important ports along the Brazilian coast. The distinguished men at that time at the head of affairs in the Empire of Brazil no doubt thought that that was not too heavy a price to pay to give Brazil some years earlier than she could otherwise have obtained them, the important benefits that would result to her from connections with the telegraphic network of the world. The erection of the Brazilian telegraph system, the internal system, was created—this is my point—for the service of the Government, and for the internal economic government of the country. Ultimately, the form the concession took was that it was divided into two. That was done for the convenience of raising the capital, and the Western and Brazilian Company was empowered to enter into agreements with other companies. Of course that is the Brazilian Submarine Company, because that was the only other Company that there was to enter into an agreement with. The cables were laid, and the Empire was thus placed in direct telegraphic communication with the outer world. The Director-General of Brazilian telegraphs has put us in this—well, impossible position. It seems to me, looking at our concession, that he can only increase the revenues of the State lines by taking the money out of our pockets, and that it is his interest, as a Government officer, to oppose every proposal which would tend to strengthen and improve this Company's communications. You will see, therefore, that that position constitutes a sort of *impasse*. Here is an officer without responsibility, here is a Company with certain concessions; and we say at this point it is for the Ministry to interfere. The Chairman then referred at great length to the communications which have passed between the Company and the Brazilian Government, recapitulating and commenting upon the information given on this point in the report of the Directors. He afterwards read the following "wire" which the Directors sent to their agent in Brazil, dated October 23rd:—"The Directors have reason to believe that the Telegraph Department of Brazil has complained to the Government of the competition of the Western and Brazilian Telegraph Company with the State lines of telegraph. The Board of the Company desire respectfully to point out that the cables of the Company were laid under the concession of April 26, 1873, which provides that the Company shall connect certain ports of the Empire, and which, under Article 4, paragraph 2, says:—'The Government remains perfectly at liberty to establish electric telegraph communications by land in whatsoever direction and to and from such points as it may deem most convenient, and in the mode that may appear to it best administratively, or by means of a private company. But the tariffs of the private telegraph lines which compete with those of this Company shall not be lower than those of the Company;' and Paragraph 3 of the same article says:—'On those portions of the seaboard where there may be, or may hereafter be laid down, land electric wires, in conformity with the foregoing paragraph, the parties who send messages shall be at liberty to transmit their telegrams either through the submarine cables or by the said land lines." Consequently the transmission of messages between the Brazilian ports was not only made a privilege, but an obligation, and so continues during the period of the concession. The Company, of course, could not have established these lines, nor have transmitted these messages, except under the express authority and approval of the Imperial Government. The competition, therefore, and at low rates, has been created, introduced, and continued by the Telegraph Department of Brazil, and the Company respectfully complained from the first, some years back, of this. The Directors are also given to understand that the Telegraph Department complain of the agreement between the Brazilian Submarine Company and this Company, under which they mutually agree to exchange messages not directed to go by other lines; but the first concession, under date March 25, 1870, provided that the whole of the lines as well between Europe and Pernambuco as between Pernambuco and the ports as since connected, were to be laid down and worked by one Company only, consequently no question could possibly arise as to the mutual exchange of messages over a line worked as one system, and any message must have remained on the lines of the Company, whether between Brazilian ports or between those ports and Europe. In place of this concession, and for the purpose of facilitating the raising of the money in England, the cables were divided, and one concession was given for the line, between Europe and Pernambuco, and another for the lines along the coast connecting the ports of Brazil, and these were laid under the mutual agreement to work the lines as one system, and, besides, the Brazilian Submarine Company were authorised, under the existing concession of August 16, 1872 (Clause 23), to make these communications if the concessionaires of the coast line failed to make them, which again shows that the traffic coming to the companies was intended to go throughout over the cables. Without these stipulations no capital could have been secured, all of which was perfectly well known to the Government, and has subsisted ever since. The Company has acted loyally and strictly within its privileges and obligations as approved and imposed by the Government, and respectfully refers the Minister to the official documents cited." On October 28th they also telegraphed to their agent:—"The Board of the Western and Brazilian Telegraph Company have just read in the Brazilian newspapers a copy of the report made by the Director-General of Brazilian Telegraphs to the Government Public Works Department upon the 'insufficiency of present telegraph lines,' *i.e.*, State lines of telegraph. The Director states that the telegraph works with rare perfection, but that the service of paid telegrams is excessively delayed owing to the excessive use of the State lines on the public service, and that merchants consequently use the cables. In other words, the State lines render invaluable service to the Government of Brazil in respect of the economical and efficient government of the country, and thus adequately fulfil the highest purpose of their creation, and thus give a return of the most valuable kind for, and meet the purpose of their erection, but are insufficient for competition for paid messages with the cables. The Director-General further states that additional wires are necessary in view of the international service which the Government undertook, not only in adhering to the St. Petersburg Convention, but also in the competition opened for an American cable. The Directors would respectfully urge that there is no American cable, and that all the obligations of the St. Petersburg Convention are met by the present service. The Director-General then proposes a further expenditure of seven hundred contos, with the object, as appears, mainly of impelling the Government upon the unfair course of an ardent war of competition with the cables with the resources of a powerful State at their back, and places as the first necessity to be provided for the 'international service of telegrams.' The Director-General further states that he has protested against the Company for reductions made step by step, as 'was forced by reductions made in the tariffs of the State lines,' although he thus himself admits that the reductions were forced upon the Company by the reductions initiated on the State lines, and that, consequently, the Company must have followed, or lost—as it did in fact lose—a large part of the business duly authorised by the concession. The Ministry of Public Works appear to have granted the Director-General the credit demanded. The Board of Directors of the Western and Brazilian Telegraph Company, as far as respects the competitive purpose sought to be attained, cannot too strongly protest against this unfair action. On the one hand the Company have so far been refused permission to adopt the best means to work their system the most efficiently, and on the other the Telegraph Department of the Brazilian Government are granted large sums to enable them to enter upon a career of intensified competition, in which the money of the State is to be now specially invested. The Directors venture to hope that the High Imperial Government will reconsider this unparalleled step, and that it may not be irrevocable, as it would constitute a most unfriendly action towards British capitalists, who, confiding in fair treatment by the Government, have invested such large sums in aid of the development of Brazil, and the Directors would further respectfully urge that benevolent consideration should be given to their representations made to the Government." Another important telegram was sent to their agent on November 5th. It was as follows:—"5th.—The Directors of the Western and Brazilian Telegraph Company have been further informed that tenders have been received by the Government for the laying of a cable or cables between Brazil and North America. The Company have already in their message of October 28th drawn the attention of the Imperial Government to the fact that the Imperial Telegraph Department states as the first reason for a further large special expenditure *re* additional wires, 'the American cable and the international traffic,' and this Company is, therefore, driven to conclude that the international traffic alluded to must be that of the Provinces served by this Company, as there is so little other. Under these circumstances, the Company desires respectfully to call the attention of the Imperial Government to Clause 4, paragraph 1, of the Company's concession, which is as follows:—'During such period no other submarine telegraph may be established from any point where the Company may have stations, as indicated in this contract, to any other point similarly circumstanced, throughout the whole extent of the northern and southern lines respectively. This disposition not excluding the Government the power to authorise other undertakings to establish submarine cables communicating between intermediate Provinces of the Empire, provided that such provinces are not included in the number of those which, in accordance with this concession, shall have communication by the telegraph line of the present enterprise.' It is absolutely clear from this Clause that during the existence of the Company's present concession no submarine cable may be allowed to establish communication for messages with the provinces which have communication by the telegraph lines of this Company, and that consequently any concession given to any such company enabling them to compete with the Western and Brazilian Company for messages in the provinces having communication with the line of the Western and Brazilian Company would be an evasion of this Company's concession. The Directors also respectfully point out that Paragraphs 2 and 3 of the same article in no way restrict the above rights, but bear them out, because the public are only given the privilege to send their messages by the submarine cable, or by the said land lines, and there is no right to send them by competing cables. In so far as such American cable may be confined to the service of provinces not served by this Company, this Company's observations do not apply. The Directors desire once more to urge the benevolent consideration of the Company's case upon the Imperial Government." To these telegrams we have had no reply yet. I have now placed our position in this matter before you. It would have been madness for us to attempt to lay these cables. It may be that, when all these thing are carefully considered, it will be seen that the Telegraph Department has not been, under the circumstances, the safest adviser for the Government to listen to. Under any circumstances, we shall continue to urge your case. We got a clause inserted in the agreement we made with the Telegraph Construction and Maintenance Company by which, if we were prevented from laying the cable, we should be free from ordering it, and have no penalties to pay. The Telegraph Construction Company met us very liberally. Our

Digitized by Google

position is financially, you will see, not unsatisfactory, and if we do not lay these cables we shall not have to issue £50,000 of debentures or sell funds out of the reserve. We are not only threatened with the competition of the American cable referred to in the telegram I have read, for there is a proposal to lay a cable from the territory of the Argentine Confederation the whole way to Europe. Before I sit down I think I ought to tell you that although we have maintained our dividend down to June 30th, we are not likely to maintain it this half-year because the revenue is extremely unsatisfactory, and the breaks have been frequent. Of course with regard to this question of the next dividend, something will depend on what the remaining period of the year produces. I might mention that the cause of the interruptions of the cables are, as far as we can see, mechanical. He concluded by moving the adoption of the report and the payment of the dividend mentioned.

Mr. C. W. EARLE seconded the motion.

In the motion which followed, Messrs. W. Griffith, Coppin, Gover, Jackson, and one or two other shareholders took part.

The CHAIRMAN, in replying to one question, stated that their concession had still some 40 years to run. He then put the motion, and declared it carried unanimously.

A vote of thanks to the Chairman and Directors closed the meeting.

West India and Panama Telegraph Company (Limited).

The twenty-fifth ordinary general meeting of the members of this Company was held at Winchester House, Old Broad-street, on Wednesday last, Mr. C. W. Earle in the chair.

The SECRETARY (Mr. R. T. Brown) read the notice calling the meeting and the minutes of the last meeting, which were confirmed. The report of the Directors was taken as read.

The CHAIRMAN: Although a Submarine Telegraph Company only able to show an available balance for distribution at the rate of 3½ per cent. cannot be called a very successful enterprise, I think that the old shareholders of the West India and Panama Telegraph Company will look at this report which we present to-day with some satisfaction. It is, as a matter of fact, the best report in its results that we have ever had the honour of laying before you. There is an increase in the traffic revenue over that of the corresponding period of the previous year of £672, which is satisfactory. It does not bring the traffic of the past half-year up to the best we have had; but the last report that was better than the present in point of traffic was in 1885—a good long time ago. There is a slight increase in the working expenses, caused by the incidental fluctuations to which the working expenses are exposed in the increase of the length of service on the part of the staff, and there is a decrease of £3,459 in the expenses on repairs. That is a satisfactory item, which I hope now will be continued. Our average half-yearly cost of repairs for the half-year has been about £13,000, but this half-year it is about £11,000; so we are £2,000 under what we have been spending on the average. As to the detailed items in abstracts "A" and "B," I do not think there is anything that I need take up your time to remark upon; but if there is any question that any shareholder wishes to put, I shall be very glad to answer it. With regard to our present position and the immediate future of the Company, I feel that it is touching on rather ticklish ground. There is a great deal that comes before the Directors in the daily management of an affair like this that it would certainly not be expedient to talk about. Very often dangers we see in the distance may be made near by any allusions from the chair. At the same time, there has been so much correspondence coming through inflated views as to what our prospects are, that I think for the safety of the concern, especially in regard to its position as to the subsidies of the colonies, it is essential that I should caution the shareholders against too exaggerated views of what our possibilities and probabilities are. Our political horizon in the West Indies is never entirely free from clouds. You must know that a great part of our revenue depends upon subsidies, many of which are voted annually by assemblies popularly elected. At those meetings we cannot be present. We are not represented, and there is an old French saying that "the absent are always in the wrong." There are several parties about the world who are interested in coming in where other people have been established before, and therefore we sometimes find that very strange mis-statements and garbled accounts are given to those assemblies of what is the existing condition of the telegraphic service of the country. I may tell you that in one of our principal colonies not long ago it was stoutly maintained that there was only one cable landed on their shores, whereas there had been two cables for the past ten years; and this statement was believed in, and added to the obloquy which certain parties tried to cast upon the Company and its operations. We have, as I before told you, got a French company that is not inactive in those waters now. There are two French colonies — French colonies are extremely patriotic — and if they could see the tricolour flag flying where the Union Jack had been hitherto, they would very likely throw us over if that result were to be brought about. I mention these things, though there is nothing we anticipate adversely, rather to keep down any excitement that our comparative prosperity may bring about. I know that for the good working of the concern, for its happy position hereafter, for its favourable position in regard to the subsidies, it is very necessary that no inflated ideas should go forth as to the prosperity of the Company. What could be more injurious than that it should go forth to a Colony, perhaps not rich, that this Company was going to pay 4 or 5 per cent? "Why," they would say, "is not this a good opportunity to stop the £500 a year we give them?" I think the dangers are clear that any exaggerated views of our prosperity may bring about; and I hope the shareholders will keep themselves cool about the price and value of our shares. I have nothing more to say, but I should be glad to answer any questions. I now move:

"That the Directors' report and accounts to June 30, 1889, submitted to this meeting be and are hereby received and adopted, and that, as recommended by the Board, a payment of 12s. per share on the First Preference shares, being 6s. the balance of arrears and 6s. dividend to June 30th, and 10s. per share on account of arrears of dividend on the Second Preference shares, be and the same is hereby declared."

Mr. WILLIAM FORD: I rise to second the resolution of the honourable Chairman. During a period of 15 years—that is, from the time when this Board was called upon to assume the management of this unfortunate Company—it has devolved upon me (with few exceptions) to second at our half-yearly meetings the resolution for the adoption of the report and accounts. I have generally done so in the usual conventional formula, but there have been occasions when from circumstances at the time I have deemed it expedient to supplement the speech of my esteemed friend the Chairman by a few remarks, and with your concurrence I propose doing so on this occasion, because I think at this juncture we may justly and profitably do a little of what I will call stock-taking as to the present position and prospects of this Company. To put myself strictly in order, I beg to second the motion of my friend the Chairman. But in doing so I feel justified in interpolating the significant words with much satisfaction. It is very rarely indeed at our meetings that I could have used these words, and I think it due to those shareholders—to the shareholders I may say generally, but especially to those original shareholders who, during so many trying and disheartening years, have stood by this Board, trusting that their labours would eventually result in something like an approximation to a dividend upon the ordinary shares—I say I think it due to them that I should state specifically the grounds of my satisfaction. Gentlemen, my friend the Chairman has referred to one which is of considerable importance. It is referred to in the report, namely, that after the lapse of twenty years' submergence of our original cables in the treacherous coral and volcanic regions of the West Indies, the cables are in efficient working order. Further, my satisfaction is that we have, by the expenditure of no less than 1,600 miles of cable, costing a sum of £337,126 in repairs, and in deviations of some of the cables from dangerous into safer bottoms, so strengthened and vitalised the system that I think we may rely upon its doing good work for us for many years to come. Another satisfaction I feel is that the duplicate cables, which in length amount to, I think, 1,520 miles, and which were laid for the purpose of enabling us in the event of any breakages of parts of the original cables to preserve telegraphic communication and perform our contracts with the Colonies, are also in good working order. Another ground for satisfaction I have is this, that we have two well-found repairing ships in the West Indies, admirably captained and officered, prepared to do any repairs and work which the Board may call upon them to do. And while I am upon this subject, I really think it due to the present captains and staff of those ships to say—and I say it in the presence of such experts as Sir James Anderson, Mr. Andrews, Mr. Holmes, and Mr. Weaver—that the repairs have been effected in a most satisfactory and prompt manner [Sir James Anderson: Hear, hear.] I think it but just to the gentlemen who have commanded our ships, and in whose hands we are very much as to our repairs, to mention this. There is another ground of satisfaction which I have, and it is that we have in our ships and tanks cable of the value of £16,000, which I hope will be sufficient for some time to come. Well, now, gentlemen, I come to another point. We have succeeded after many laborious years in bringing together a substantial reserve fund, and what is more, we have succeeded in preserving it from the hands of the would-be spoliators. I say would-be spoliators because some gentlemen have come into this Company when the ordinary shares were under £1, not for the purpose of dividend, but for the purpose of giving a temporary value to the shares by endeavouring to obtain a portion of that reserve fund for division amongst the shareholders. We have withstood that, and shall continue to do so. I now come to what I may consider the last—I could mention others—and, in my opinion, the most important ground of satisfaction, and it is this: that we are now earning and receiving—and I lay stress on the word *earning*—the original subsidies, less the amount which St. Vincent and St. Thomas were obliged, by reason of the embarrassed condition of the finances of these islands, to withdraw, but plus the generous and much-needed additions by St. Lucia, Granada, Trinidad, Demerara, and the grant by Jamaica. Now, this is the first time in the history of this Company that these several circumstances to which I have adverted have been *co-existent*. True it is they have been growing from time to time, but this is the first time they have been co-existent, and it is therefore the first time that their cumulative force and effect upon the future of this Company and upon its present position could be taken into consideration. I said cumulative. We must make them for the future concurrent, because I do hold this, that if you withdraw from this fabric, which we have been for years building up, any of these favourable circumstances you endanger the stability of the whole edifice, of which I hold that the subsidies are the corner-stone. Gentlemen, I fear lest I should weary you, but since we came into office a new generation of shareholders, and, I may say, a new generation of colonists, have come into existence who know not Joseph; and they require to be reminded, and must be reminded, of the circumstances under which our original capital was subscribed—of the circumstances under which three-quarters of a million of further capital were subscribed to enable us to fulfil our obligations to the colonies in respect of which the subsidies were granted. It has been mentioned before, but I do not think it can be mentioned too often—it must always be kept before the shareholders, old as well as new, and before the colonists—what were the conditions, what were the terms, upon which this orignal capital was subscribed? They are contained in the pros-

Digitized by Google

pectus of the Company which I have before me. The prospectus estimated the traffic of the West Indies—that is their messages—at £156,000 per annum. Those estimates were sanctioned, or were countenanced, by gentlemen of the highest commercial standing in the West Indies. The Colonies, or, rather, those who represented the Colonies, were well acquainted with all these facts, and with the knowledge of such facts they granted the subsidies. Now what has been the result? Instead of a revenue of £156,000, at no period of the existence of this Company has it amounted to much more than one-third of that sum, and for some years considerably less, and for the whole period the average has been under one-third, whilst the working expenses have been, notwithstanding the most frugal management, more than double the prospectus estimate. I say, therefore, that it is our duty to insist, as far as it is possible for us to do so, that there should be reciprocity upon the part of the colonists in consideration of the great sacrifices which the shareholders of this Company have made. I do wish that those gentlemen who take upon themselves to enlighten the public by communications to financial newspapers, and who say that this Company is about to enter the dividend list—I do wish that they could give the public the whole truth, not partial truths. They are so exceedingly misleading. What are the real facts? I hold, after those representations upon which the original capital was subscribed—and upon which I omitted to mention it was estimated that the traffic, with the subsidies, would produce a dividend of upwards of 20 per cent. to the shareholders—that until the original shareholders of this Company have received something like an approximation to the amount of dividend they expected, plus a dividend for the current year, the West Indies have had the best of the bargain, and that we, by means, have had the worst of it. Certainly, we find ourselves after 20 years' establishment of this Company in an infinitely worse position by some millions than we were at the commencement. I assure you that this statement is not a *lapsus*—it is not a figure of speech. It is a word that can be demonstrated in figures, and in two or three words I will do so. The original capital was put at £650,000. The present capital of the Company is £1,200,000 odd. I have, therefore, got more than half a million. But now take what would have been the interest due on the ordinary shares of the Company if anything like an approximation to the prospectus had been given. This would have been the result: that we should have received in dividends, at 20 per cent., no less a sum upon the original capital than £2,256,000, or upon the increased capital £3,066,000; but let us come down from the altitude of 20 per cent. to the commonplace level of 5 per cent., and you will find that upon the original capital the result is £564,214, and upon the increased capital £766,500, in respect of which the ordinary share have received only three dividends of 1s. each. These are astounding figures, but they represent the sacrifices which the shareholders have made for the benefit of the West Indies, and to enable the Company fairly and properly to carry out their obligations upon which the subsidies were granted. It may be said—the Chairman adverted to it—that if a glowing account of the possible future of this Company should go abroad it may tend to a consideration in the West Indies whether we are able to stand alone without subsidies. Pray consider what I have said before, that the advantageous position, if such you may consider it, in which we stand at the present time is dependent upon the continuance of the favourable circumstances I have mentioned, because, as I have said before, if you withdraw one of them, the stability of the whole fabric is in danger. I could have said a great deal more, but I assure you that I could not conscientiously have said less, because I think something was due from me to those shareholders who, so many years ago, supported me in the struggle which led to the appointment of this Board.

Mr. FITZGERALD asked whether the Directors could see their way to the employment of one steamer instead of two. It was allowed at a former meeting by the Directors themselves and by the Chairman that if that state of things could be arrived at, there would be a very large saving indeed. He saw that during the last half-year one of the vessels was employed 82 days out of the six months, and the other vessel, the "Marlborough," was employed out of six months 36 days. He knew that the Chairman explained on the last occasion that there were dangers of losing the subsidy, but still if one vessel could be employed there would be a very large increase indeed in the amount available for distribution. And, moreover, a vessel, especially a steamer, deteriorated almost as much when it was not, as it did when it was employed. He also desired to ask the Chairman, whether in his opinion the time had not arrived when the present reserve, amounting roughly to £150,000, would be sufficient—with the interest it earned added to it every year—without drawing upon the earnings of the Company for further additions to the fund.

The CHAIRMAN: With respect to the question about the steamers, I can only repeat what I stated at the last meeting, that we should be very glad to get rid of one of the vessels. You will notice that one of them had to come to England for repairs.

Mr. FITZGERALD said that that made his argument rather stronger.

The CHAIRMAN: I do not know what we should have done if we had had to bring that vessel home without our having another one there. I do not think myself that at present we should be justified in doing away with one of our ships. It would be pulling out one of the stones of the fabric to which Mr. Ford referred. There might be a breakage of one of the cables, and there would be an agitation in the West Indies and a stoppage of subsidies, so that the saving would be very dearly paid for. What we shall be able to do in the future when we have the other two cables to Demerara and Barbadoes duplicated I cannot say. These cables are single, and we have to keep a ship about there to watch them. The other one is at St. Thomas, where it is more in accord with the main trunk line. If these two cables were duplicated it might be a question whether there should not be some modification. In reply to a question, he added: The length of one of the single cables is 300 miles, and of the other 100 miles, but the duplication would bring us no more traffic. With respect to the reserve fund, the whole of the amount is not reserve strictly speaking—it is reserve to meet depreciation, and every year a certain amount of deprociation occurs, which has to be met if we are to conduct our affairs on proper business principles. I should also say that a strong reserve was, independently of the question of depreciation, a most valuable thing for us in every way, in view of possible opposition, and to stop insane competition. It is insane to compete for traffic that cannot properly support one cable, and to lay another cable is insanity. I think, therefore, the existence of a good strong reserve which would enable you to fight is most likely to keep out anyone who has any sense upon the subject. He then put the motion in the usual way, and it was carried unanimously.

A vote of thanks was then passed to the Chairman and Directors, and in reply

The CHAIRMAN said that he would like to include in the compliment their excellent staff, both at home and abroad. He assured the shareholders that they had the services of a most able body of men.

The proceedings then terminated.

The Swan United Electric Light Company (Limited).

The seventh ordinary general meeting of the shareholders of this Company was held yesterday at the Cannon-street Hotel, Mr. J. S. Forbes presiding.

The SECRETARY (Major S. Flood Page) read the notice convening the meeting, and the Directors' report and statement of accounts were taken as read.

The CHAIRMAN then proceeded to give an analysis of the accounts, and said that the stock in hand on October 1st was £9,676; purchases, office expenses, Directors' fees, rent, salaries, and Mr. Swan's salary, amounted to £4,194. Wages and expenses at factories figured at £5,290, depreciation at £1,863, sales ledger reserve at £100, and the balance at £21,042. On the opposite side of the accounts they would find by sales, less commissions and allowances, £17,665; transfer fees and interest, £1,344; dividend to December 31, 1888, received from La Compagnie Générale des Lampes Incandescentes, £885; dividends to June 30, 1889, received from the Edison and Swan United Electric Light Company (Limited), less income-tax, £20,117; and stock, September 30, 1889, £3,770. In the last item it would be seen that there had been a considerable diminution from that of the corresponding heading on the debtor side brought forward on October 1st, amounting in round numbers to £5,000. The explanation of that item, as he had had from time to time occasion to mention, was that the Company could not carry on its business without having in hand ready for supply a great number of lamps of the various types which were required in the business. Those lamps, of course, must be manufactured and perfected and kept in store, and according to the volume of business would be the proportion of those lamps to those which had been manufactured and sold. Another reason why the figures diminished was that they had thought it prudent in the valuation of those lamps to bring them forward at 1s. instead of 1s. 3d. per lamp, for the reason that the cutting price in Germany was still going on, and it was deemed better to meet that possible depreciation of sale price by a corresponding reduction in the value of the lamps. They knew that the Company had parted with their patents, or rather with their separate existence as patentees, with respect to a considerable portion of their Continental business, to a company in Paris, of which they were members, La Compagnie Générale des Lampes Incandescentes, in which, in virtue of their amalgamation with the Edison Company, they received a certain consideration in the shape of shares for a portion of the value of their patents and business, and in which they subscribed a certain sum of money, £16,000, whereby they were the owners of 40 per cent. of that undertaking. Although that company had been in operation for a short time the result had been that a dividend had been declared to December 31, 1888, amounting to 6 per cent. They might congratulate themselves on the dividend to June, 1889, received from the Edison and Swan Electric Lighting Company (Limited). This was the first occasion on which the Directors of that Company felt justified in apportioning any portion of the profits of their undertaking to the purpose of dividend, but they had done it with perfect confidence in its legality and wisdom, and, as would be remembered, they declared a dividend of 7 per cent. on the capital invested, and 3 per cent. in addition, in the nature of a claim for contingent value in the Company, because the 7 per cent. was cumulative, and had to be satisfied out of the profits before the Deferred shares could receive anything. As they knew, for a number of years the Edison and Swan Company, like themselves, had to write down losses incurred in the initiation of the business in former years, and it was not until these losses were written out that they felt themselves free to determine to pay a dividend; but for the dividends payable by the Edison and Swan United and La Compagnie Générale des Lampes Incandescentes, they would have had nothing to divide. Their profit for the year came from the interest they had in those two undertakings. In other words, the Swan United existed principally as owners of shares in the Edison and Swan Company and in La Compagnie Générale des Lampes Incandescentes of France, which meant a combination on the Continent of Europe of the same character as that which had been so successful in England under the guise of the Edison and Swan United Electric Light Company. La Compagnie Générale had got all Europe, except Germany, before them. They had got an admirable factory, and there was every reasonable ground for believing that they would go on doing on the Continent, as had been done in England, a large business, resulting in considerable profits. So the Swan Company's separate manufacturing business was now limited to the Kalk factory, near Cologne, Germany, as he had explained when they were good enough to sanction the amalgamation being excluded from it for reasons which were then made clear. They had the Kalk factory on lease, which terminated next June. Between

Digitized by Google

now and then they would have to consider whether they would go on with the manufacturing of lamps there, or whether they should try and find—as they had been doing in fact—in Germany any combination to whom their interests might be handed over, or with whom they might become partners, on advantageous terms. Judged as it stood by the sales and the expenses, it was a very bad business, but those expenses could be materially reduced, because they had been able to re-arrange the German business since their fusion with the French company, by which they were already assured of a considerable reduction in the fixed charges during the current year. Depreciation, £1,863, was a larger item, but it was a precautionary measure. They thought it possible that circumstances might turn out to justify or require the abandonment altogether of the Kalk factory, which might entail some loss, and it was deemed advisable to write down the plant from time to time. The balance of £21,000 was profit on the year's transactions, which they could now recommend for division. They had had reasons, from time to time, for withholding the profits earned, because there were certain outstanding questions connected with the German business which made it desirable to reserve a substantial sum. They knew there was litigation going on for infringement of patents, and the process was exceedingly slow and unsatisfactory. It was possible in the course of time that they would be made out to be infringers and be liable to damages. No human being could say what those damages would be. By the German law they had had to deposit in the hands of the German Government about £5,000, but that sum might or might not be sufficient to meet the damages if there were any. Coming to the balance-sheet, he said he had no remark to make on capital, it being exactly as it was last year. On the opposite side, they would see by cost of patent rights, &c., represented by shares in Edison and Swan United Electric Light Company (Limited), with £208,478 paid; shares in La Compagnie Générale des Lampes Incandescentes, with £30,489. 8s. 3d. paid; patents held by the Company for Germany, India, &c., as per last balance-sheet, £329,911. 17s. 8d. That was what they invested in this Company, which in turn had invested in those two other allied companies. The additional expenditure thereon, £422, was spent partly on the patents themselves and partly on small legal expenses connected with them. They had reduced the outlay on factories, plant, &c., to £2,453. Sundry debtors, £3,324, were all good debts, and would more than set off the sundry creditors on the opposite side. Their investment in Prussian Consols cost £5,120, and their investment in New Two and Three-Quarter per Cent. Consolidated Stock cost £29,004, while they had cash on deposit and in hand £38,046. The report summed up the story he told them as follows:—"After paying all current charges, and making ample allowance for depreciation of plant, there is a credit balance of £21,042. 8s. 1d., to which must be added the credit balance of £10,052. 8s. 11d. brought forward from the last accounts, making a total of £31,094. 17s. The Directors will recommend the shareholders to declare a dividend of 6 per cent., which will absorb £22,208. 0s. 9d., to be distributed to the shareholders in accordance with Clause 77 of the Articles of Association." Having alluded to the possible collapse of the export trade from England, owing to cheap labour in Germany, and to the trade combinations, high rates of wages, and the uncertainties of manufacture in this country, he proceeded to say that that was a red-letter day in the history of the Edison and Swan Company so far as the Directors were concerned, because the shareholders could easily imagine what they felt when there was some dividend to pay in contrast with the dreary years they had passed through, with all their legal and scientific troubles to contend against, and no returns. He thought they were standing on safe ground. He trusted they would be satisfied with the state of things for the last year and with the outlook for the future. He believed the Edison and Swan report was sent to every proprietor. Well, they could see from that that they had very good prospects, a sound business, with patents—as far as they knew—invulnerable, with a lamp which increased from day to day in efficiency, and a large and growing output. The electric light, moreover, was now alive. There were companies now at work risking enormous sums of money upon every kind of device for giving London the benefit of the electric light. The shareholders of the Company would be the first to benefit from that, because those companies could not light without them. It seemed to him that the future was very hopeful, and probably in a few years the proprietors in both Companies would be amply repaid for the patience they had displayed and the positive loss they had incurred in being without dividend.

Mr. F. R. LEYLAND seconded the motion, explaining that the French Company were trying to do what had been done in the Edison and Swan Company—that was to say, they were litigating their Edison patent, with a view to establish it. That would be found, of course, troublesome, and to some extent risky, but if they succeeded in establishing their patent in France, as they established theirs in London, there was a career open to the French Company superior even to that of the Edison and Swan Company. That was where they would get their returns from.

Mr. A. SKAIFE asked whether there was not now on the market a great competitor in the shape of a lamp which had been taken up by Mr. Edison?

The CHAIRMAN said he was not aware of the existence of any such lamp, but if Mr. Edison did produce a new lamp he was bound to give them the benefit of the patent, being, as he was, enormously interested in this Company. He could not believe that Mr. Edison would go on improving the manufacture of the lamp and throw it open to all the world, to the detriment of his own property.

The resolution was carried unanimously.

On the motion of the CHAIRMAN, seconded by Mr. LEYLAND, the following resolution was also adopted unanimously:

"That the following dividends be declared for the year ended September 30, 1889, namely, a dividend of 6 per cent. per annum on the amount of £3. 10s. per share, being the amount which has been paid on the partly-paid shares, and of 5 per cent. on the fully-paid shares, and an additional dividend of 1 per cent. on the fully paid shares, reckoned for the purpose of this additional 1 per cent. as if £3. 10s. only had been paid on each of such fully-paid shares."

Mr. LEYLAND then proposed, and Mr. SWAN seconded in a few complimentary terms, the re-election of Mr. Forbes to his seat at the Board.

The motion was cordially agreed to, and

The CHAIRMAN, having briefly returned thanks for this renewed mark of confidence, proposed the re-election of Mr. E. W. Batt to his seat at the Board.

Mr. LEYLAND having seconded the motion, it was agreed to *nem. con.*

Subsequently the Auditors, Messrs. Welton, Jones, and Co., were re-appointed Auditors, and a vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

Woodhouse and Rawson United (Limited).

The first general meeting of the shareholders of this Company was held on Tuesday, at Winchester House, Old Broad-street, under the presidency of Sir Rawson W. Rawson, K.C.M.G., C.B.

The SECRETARY (Mr. Malcolm J. R. Dundas) having read the notice calling the meeting,

The CHAIRMAN said: Gentlemen, my first duty to-day is to convey to you the expression of the regret—extreme regret—of our esteemed Chairman, Lord Aberdare, which he forwarded to us in a note two days ago, that he was not able to attend this meeting. Some of you may be aware that he had a very serious illness just about the time of the formation of this Company, which confined him for a long time to his house in South Wales, and he is not able to come up to London for the

express purpose of this meeting. My colleagues have done me the honour to ask me to fill his place—very inadequately, I fear—on this occasion. But the duty is so simple that perhaps I may not have a difficulty in acquitting myself of it. Our object in meeting to-day is to comply with the legal formalities of a statutory meeting within a limited time after the formation of the Company. We have not to ask your approval of any proposals to-day, but simply to report to you that all the essential formalities connected with the constitution of the Company and the amalgamation of the businesses of the several companies which are now united in this one have been completed. The attention of the Board has been necessarily directed mainly to that object, for there was a great deal of complication, as you can well imagine, in amalgamating, combining, and organising the business of so many companies, and such a variety of businesses—a manufacturing business, a supply business, a contract business, and foreign businesses. It has been a labour for the Directors which they have gladly undertaken, and which I hope they have successfully accomplished. We have also had the material difficulty of removing our old offices from the premises occupied by Woodhouse and Rawson (Limited) to those which we have now engaged, in a most convenient situation, and, notwithstanding that, we have the whole of the building to ourselves, I am happy to say, at a very slightly increased expense, close to the Mansion House Station, at 88, Queen Victoria-street. The premises look both into Cannon-street and Queen Victoria-street, and they are very capacious. They seem almost peculiarly adapted for a business of our nature, there being an extensive warehouse below and large rooms above the offices, where we can keep our stock, and, we hope, satisfy all our customers who come to us for electrical supplies. The Directors have made the shareholders acquainted with the circumstances of the Company from the beginning. In our circular of August 2nd we explained the circumstances that had delayed and hindered the original allotment of the shares. We have since informed our shareholders that a very important and very profitable contract, which was in negotiation at the time of the formation of the Company, has been completed, and promises as profitable a result as that which distinguished the last year of the existence of Woodhouse and Rawson (Limited). The business was one of the matters taken over by us incomplete; it has since been completed, and it justifies us in assuring you that the prospects held out in the original prospectus may, or rather will, be realised. You know that you have the security of the original Company for a guaranteed dividend for the first three years, by having placed in our hands a large deposit to be used as working capital beyond that realised from our own shares, so that by the end of three years we shall have got into a very large and profitable business. There has been perfect evidence of the wisdom of the original Company extending itself in this direction. We have by organisation economised very largely the costs of administration. By the possession of increased capital we have received large offers—important offers—of business which were not likely to be offered to the other Companies because they would not have had the capital to carry them out, and if they had been offered, they were not in a position to accept them. We may do so now, and with our existing capital I can safely say, on the part of myself and co-Directors, that the business now in hand offers a realisation of what the promoters of this Company held out. I was not one of the promoters, for I had no connection with it in its original form except from the fact that my son was interested in it. I was interested in his success, of course, but I was in no way concerned in his commercial undertakings. I am now interested in it, and I feel my co-Directors have also manifested a very sincere and earnest interest in the success of the Company, and I think I may honestly say to you that the prospects before the Company are quite as good as they were held out in the original prospectus, and in the more recent one that was published on the occasion of our issuing a fresh number of shares at a premium. I do not think I have anything more to say to you. What we had to say has been said in our several addresses to our constituents; an important point I may here say, is that what we have there said has been confirmed by our examination and by our work during the last four months. In conclusion, for I need not detain you further, I would draw a happy omen from the title of our Company. We are now not merely a limited company, but a united company. I may say for my colleagues on the Direction that we are thoroughly united, and I hope they will confirm, if necessary, what I have stated to you to-day, and I sincerely hope that when we meet, as I trust we may before long, to address you more particularly with regard to the details and earnings of the Company, we shall be able to make such a statement as will insure not only a united body of Directors, but a united body of shareholders also, and that we may receive their support, and derive all the advantages we hope to obtain from it. I shall be happy, to the best of my ability, to give information, if any one requires it, but otherwise the business of the present meeting is concluded.

Sir J. STOKES, K.C.B., fully confirmed all that Sir Rawson Rawson said as to the position and prospects of the business. Having been engaged in the business of the old Company for the last few years, he was, perhaps, in a good position to say that he thought things now looked even better than they had ever done before.

The CHAIRMAN said that if the shareholders desired to ask no information, that was the end of the meeting that day. They would meet again at an early period, perhaps at the beginning of the year.

NEW COMPANIES REGISTERED.

LANGE AND CO. (LIMITED).—This Company has been registered to acquire the business of Lange and Co. at Boulogne-sur-Mer, and to carry on the business of electrical engineers. Capital £10,000, in £50 shares. Amongst the subscribers of one share each is Mr. George H. Verity, 31, King-street, Covent Garden, who is also one of the first Directors.

THE PRIESTMAN OIL ENGINE AMERICAN SYNDICATE (LIMITED).—Objects: To purchase the Priestman and Hume's patents relating to hydro-carbon engines for the United States of America, and there to carry on the business of mechanical engineers, iron founders, and engine builders, and makers and dealers in electric power and lighting. Capital £25,000, divided into 1,250 preference shares of £10 each, and 1,250 ordinary or deferred shares of £10 each. Preference shares confer a right to dividend of 10 per cent. Directors, not less than five nor more than seven. First directors: E. P. Maxted, John Sherburn, Harrison Holt, James Reckitt, Samuel Priestman, and Joshua Priestman.

THE TRANSVAAL OIL ENGINE COMPANY (LIMITED).—Objects: To acquire patents rights for inventions in petroleum engines; to ratify an agreement between the Hamilton Syndicate (Limited) and Alfred John Cooley; and to carry on in the Transvaal or elsewhere the business of mechanical engineers, manufacturers of engines, and workers and dealers in electricity, motive power, and light, and so on. Capital £25,000, in £5 shares. Directors, not less than two nor more than five, to be appointed by subscribers.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The receipts of this Company for the week ended November 8th amounted to £4,636.

CROMPTON AND CO. (LIMITED).—An interim dividend, at the rate of 7 per cent. per annum, has been declared by the Directors of this Company for the past half-year, payable on December 14th next, carrying forward a balance of net profits for the half-year sufficient to pay the preferential dividend at the same rate for the next half-year.

GREENWOOD AND BATLEY.—The Directors have declared the following interim dividends for the half-year ended September 30th, payable on the 14th inst.:—At the rate of 7 per cent. on the Cumulative Preference, and of 10 per cent. on the ordinary shares.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 8th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,172.

WOODHOUSE AND RAWSON UNITED (LIMITED).—Letters of allotment and regret have been posted.—This week the Company have gone into their new premises at 88, Queen Victoria-street, London, E.C., to which address all communications are in future to be sent. We are also desired to announce that the firm's telephone number is now 1978.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

FACTORY.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 601.—Vol. XXIV. FRIDAY, NOVEMBER 22, 1889. Price Fourpence.

NOTES.

We are pleased to notice that our correspondent "Telegraphy" is this week a little less irreconcilable than appeared from his first letter. The grievance to which he has given such vigorous expression will now probably be removed, and a fuller representation secured for the varied interests concerned with electrical science.

After a lengthy debate the Edinburgh Town Council has by 25 votes to 8, approved of the minute passed at the last meeting, embodying a resolution the practical effect of which was to leave it open to the Corporation either to apply for an electric lighting Provisional Order on its own account, or to enter into an arrangement with one of the six companies who are competing for the honour and profit of supplying Edinburgh with the electric light. The debate was only noteworthy in so far as it brought out in a very clear manner that many of the members of the Edinburgh Town Council are haunted with the fixed idea that the granting of a Provisional Order to a private company means a 42 years' monopoly, and the tearing up of the streets in all directions without let or hindrance on the part of the local authority. Many of the local authorities have thus been induced either to take up an unreasoning attitude of opposition to the introduction of the electric light, or to lodge applications for Provisional Orders without any intention of using their powers when obtained. A cursory study of the Electric Lighting Acts, and of the model Provisional Order, would, we are confident, convince members of local bodies that the progress of the electric light in this country is far more likely to be hampered by undue restrictions than that the districts under their jurisdiction will become the prey of unfettered monopolists.

If the alternate-current motor difficulty is not shortly overcome, it certainly will not be for lack of endeavours to solve the problem. We publish this week two attempts in this direction, one due to Mr. Van Depoele, of street-railway fame, and another due to Dr. Sumpner. Prof. Ferraris, it will be remembered, proposed to employ a transformer wound with two secondaries to excite his field-magnets. In one secondary there was as much inductance and as little resistance as possible, while in the other there was high resistance and small inductance. In this manner the phase of the two currents was displaced to nearly 90deg., and the copper ring he employed was rotated. Mr. Nikola Tesla obtained the same result by winding opposite quadrants of his field-magnets with two independent circuits traversed by currents relatively displaced by $\frac{1}{4}$ phase. Mr. Van Depoele winds what may be termed his primary coil on to one set of magnets arranged outside the armature, and his secondary on to another set arranged inside the armature, with poles midway between those of the external magnets. Dr. Sumpner proposes to do away with the disadvantage under which the Tesla motor labours of requiring a special third wire, by an ingenious adoption of Prof. Ferraris' device, alternate quadrants of the Tesla motor field-magnets being wound with several turns of fine and a few turns of thick wire.

Mr. Thomas D. Lockwood, of telephonic fame in the United States, has been giving to the members of the American Institute of Electrical Engineers his impressions of British telegraphy, telephony, and electric lighting, formed during a recent visit to this country. On the whole they are shrewd, appreciative, and just; while in some respects they are suggestive and instructive even to English readers. With regard to one or two points, however, his remarks will strike them as particularly odd—for example, the reflections on our Government control of the telegraphs. He is pleased to approve of it for this or any other country where the Government is monarchical, "whether limited or absolute"; but not for a republican Government, subject, like that of the United States, to "radical and sweeping changes." Mr. Lockwood could, no doubt, give us a better reason than this if he tried. The Government of the North American Continent has proved more permanent than the monarchical ones of the Southern Continent; and we never hear of the telegraphs being swept away, however sweeping the political changes may be. His real reason probably is that where politics is a trade, and spoils are to the victors, the administration of a huge Government business might be made the instrument of jobbery and corruption. That, we believe, is the view commonly expressed in America; and we are inclined to agree with it in preferring private monopolies to public plundering by political adventurers.

Both Lord Rosebery and Mr. Henniker Heaton are so much in the habit of mixing in strange society that it does not surprise us to see them joining hands on the platform of

Digitized by Google

Imperial Federation. The Conservative member for Canterbury seems to have convinced both the noble Home Ruler and the Unionist *Times* that the shortest way to secure the aims of the Federation League would be to cheapen the postal and telegraphic rates to our Colonies. This may or may not be the case, but if the whole scheme of federation is to be carried out on the same principle as the cheapening of mail and cable service—that is to say, at the expense of the mother country, we fancy that the project will not make much headway. As regards cable rates, they could be cheapened to-morrow if the Colonies would only take their fair share of the cost and the risk of doing it.

A SHORT time ago the newspapers reported a banquet of Pears' soap celebrities; last week one, if not more, of the daily papers admitted a letter from the Medical Battery man, complaining of the dirty condition of the footpaths in Oxford-street and Holborn. Intending patients could not make their way to the famous electrical hospital in consequence of the mud, and business was falling off. There probably is no doctor or physician in London who could get space in the papers for a similar complaint. But doctors and physicians, as a rule, do not advertise, and that may account for a good deal.

THE latest suggestion in the way of electrical conduits which comes to hand from Boston, does not commend itself to us as being either cheap or effective. It is proposed to employ indurated fibre pipes filled up with flake mica, and run cotton-braided wires through the ducts. We do not think the insulation thus obtained would be particularly high, and the cost of such large quantities of pure mica would probably prove prohibitive.

THE old adage that "Necessity is the mother of invention" has once more been exemplified by the Julien Company of New York. Since the rendering of the decision in the United States Circuit Court preventing them from applying active material to their accumulator plates in the form of paste or paint, this Company has discovered that dry powder, compacted upon the grid by hydraulic pressure, gives results far superior to any hitherto obtained. This is not the first time that the necessity of "getting round" a patent has given rise to valuable discoveries of that character.

WE hear that Mr. CROMPTON has turned his attention to the improvement of the Fritsche "wheel" dynamo, which was described in these columns in April last. There are some who think that in these coreless armature machines, such as the Fritsche and Desroziers (*The Electrician*, October, 19, 1888), we see the dynamos of the future—at any rate for heavy central station work; and if Mr. CROMPTON transforms this latest foreign importation as completely as he did the old Bürgin machine, its performance will excite considerable interest.

AN association is, we are glad to hear, in the course of being formed, under the title of the "Gilbert Club," for the purpose of bringing out an English edition of Dr. GILBERT'S much-talked-of but too-little-read "De Magnete." It is proposed to reproduce as nearly as possible the fine folio edition of 1600. Another object of the "Gilbert Club" will be to organise a fitting celebration next year of the tercentenary of this old English worthy. Only a limited number of invitations to join the Club have been issued, and among those who have already consented to become members are Sir WILLIAM THOMSON, Lord RAYLEIGH, Prof. TYNDALL, Prof. REINOLD, Prof. RÜCKER, Prof. FORBES, Sir DAVID SALOMONS, Mr. W. H. PREECE, and Mr. LATIMER CLARK. Prof. SILVANUS THOMPSON'S enthusiastic advocacy of the claims of the "Colchester philosopher" to immortality is well known, and he gives his support to the scheme by occupying the onerous position of honorary secretary. The first meeting of the Club will be held next Thursday, at the Society of Arts.

Barnsley.—The Corporation intend to apply for an electric lighting Provisional Order.

Wednesbury.—The Town Council has unanimously resolved to make application for an electric lighting Provisional Order.

Tiverton.—At a meeting of the Town Council on Monday it was unanimously decided to apply for an electric lighting Provisional Order.

Levenshulme.—Consent has been given by the local Board to the application of the Manchester House-to-House Electricity Company for a Provisional Order.

Madrid.—Trials will shortly be made on the different tramway lines in Madrid of the Sprague and Thomson-Houston systems, and also of an accumulator car.

Ohm Memorial Fund.—The Committee of the Ohm Memorial Fund announce that, the subscriptions having reached the sum of £125, they propose to close the collection.

Portsmouth.—It has been decided to issue at once the necessary notices of the intention of the Corporation to apply for a Provisional Order to supply the electric light.

Ballymena.—A committee has been formed to take steps to form a local electric light company. Considerable support was given to the scheme at a recent meeting in the town.

Edinburgh International Exhibition.—It will be seen from our advertising columns that the Executive Council are prepared to consider tenders for the lighting of the Exhibition buildings and grounds.

Electric Lighting Provisional Orders.—The applications for Provisional Orders lodged with the Board of Trade up to date amount to 430, and power to apply for further Orders remains open until the 30th inst.

Hamilton.—At the last meeting of the Town Council the Provost reported that, carrying out the resolution of the Council in July last to apply for a Provisional Order, the statutory notice had been prepared.

The Eastern and South African Telegraph Company.—This Company announces the drawing of 283 £100 Debentures for payment at par on January 1st next. Full particulars are given in our advertisement columns.

Ayr.—The Town Council, on Saturday, unanimously resolved to apply for a Provisional Order in order to light the town with electricity. It has been estimated that an electric installation for Ayr would cost from £18,000 to £20,000.

Swindon.—The Swindon New Town Local Board will receive tenders up to the 25th inst. for lighting, "by gas or other illuminant," the district under their authority. Further particulars can be obtained of Mr. H. Kinneir, clerk, New Swindon.

Dundee.—A joint meeting of the Town Council, Police Commission, and Gas Commission was held, on Monday last, to

Digitized by Google

consider the question of electric lighting. After considerable interchange of views, it was agreed, by 15 votes to 3, to jointly apply for a Provisional Order.

Sale by Auction.—Messrs. Wheatley Kirk, Price, and Goulty announce the sale, early in December, of the entire contents of the Victoria Engine Works, Chester; and they further notify that the lease of the works is also for sale. Particulars will be found in our advertising columns.

A New Soldering Flux.—We have received from Mr. Watkins, of Eccles, a sample of his liquid resinous flux. The solder flows very easily with this flux, and as it is said to contain no acid or alkali, it ought to prove useful for soldering connections in electrical instruments, cables, &c.

Appointment Vacant.—The Directors of the Great Eastern Railway Company will receive applications up to the 26th inst., for the appointment of telegraph superintendent and engineer, rendered vacant by the death of Mr. H. Sach, at a salary of £500 per annum. Further particulars will be found in our advertisement pages.

Cambridge.—At the last meeting of the Town Council it was decided to publish the necessary advertisements in connection with the proposed electric lighting Provisional Order and to call a special meeting of the Council for December 12th. In the meantime the whole question is to be referred to a committee, with power to consult an expert, for inquiry and report.

Electricity in Mining Operations.—About 70 gentlemen from various parts of the country accepted an invitation to visit St. John's Colliery, Normanton, on Wednesday, to inspect the electric pumping and hauling plant which Messrs. M. Immisch and Co., of Kentish Town, have there put down for Messrs. Locke and Co. Great satisfaction was expressed with all that was seen.

Newcastle.—The Chairman of the Newcastle and District Electric Lighting Company has written to the Mayor proposing that as a way out of the present legal deadlock the Company should deposit a sum of money with the Corporation, and that the Company should enter into an agreement allowing this sum from time to time to be applied towards the payment of any penalties that may be incurred by the Company.

The Preparation of Ozone.—Owing to its extraordinary oxidizing properties, ozone, if it could be produced on a commercial scale, would find many industrial uses. A M. de Vars employs, but with what success is not stated, two concentric tin-coated cylinders enclosed in a bell jar. The two cylinders are connected to a powerful source of electricity, and a current of air is passed between their adjacent surfaces, the ozone being then drawn off.

Hull.—The Corporation have refused their consent to the applications of the electric lighting companies for Provisional Orders, and the Town Clerk has been instructed to take the necessary steps for obtaining a Provisional Order authorising the Council to supply electricity for public and private purposes within the borough. A Special Committee has also been appointed for the purpose of dealing with the question of electric lighting within the borough.

Electric Traction at Plymouth.—The Plymouth Tramway Company is about to complete and equip the line for which renewed parliamentary powers have recently been obtained, and is prepared to receive proposals for traction by cable or electricity. Applications should be made before December 5th, by letter only in the first place, to the Secretary, Plymouth Tramway Company, care of Messrs. Walter Webb and Co., 28, Queen Victoria-street, London, E.C.

Proposed Electric Railway in the City.—At the last fortnightly meeting of the City Commission of Sewers a letter was read from the solicitors to the company which proposes to seek Parliamentary powers next session to construct an electric railway from Holborn, through Newgate-street, Cheapside, and ending in King William-street, asking for instructions as to posting street notices regarding the same. After some discussion, the whole business was referred to the Streets Committee for consideration and report.

C. and C. Electric Ventilating Motors.—All the motors exhibited by Messrs. Shippey Brothers (Limited) at the Birmingham Exhibition were sold. One has been fixed at a brewery in Burton-on-Trent, one for ventilating a bank in Yorkshire, two for ventilating the smoke rooms at a hotel in Manchester, and four for various circuits in Bradford, Leeds, Liverpool, and Birmingham. Ten of the C. and C. fan sets have also been fitted in the new steamship "Teutonic" for ventilating the saloons, kitchens, smoke rooms, &c., for the White Star Line.

Electric Traction at Birmingham.—Sir John Fowler, K.C.M.G., and Mr. W. H. Preece, F.R.S., having been deputed by the Government of New South Wales to investigate the question of electric traction in England, inspected on Saturday last the electric car constructed by the Electrical Construction Corporation for the Birmingham Central Tramways Company. The trial was completely successful. The Electric Construction Corporation, we may add, have received an order for twelve accumulator tramcars from the Birmingham Central Tramways Company.

Electric Traction in Brisbane.—In their last half-yearly report the Directors of the Metropolitan Tramway and Investment Company expressed the opinion that so long as horse traction was employed so long would the Company be subject to abnormal fluctuations in expenditure, and the Directors announce that requests for permission to substitute an electric overhead wire system for horse traction have been forwarded to the various local authorities around Brisbane. In addition to this a second tramway company has been formed, which proposes to work its lines by electricity.

Electric Lighting at Alnwick Castle.—The installation at Alnwick Castle will, when completed, comprise some 700 lights. The motive power is obtained from the Abbey Mill, where a 30 horse-power turbine, and a 19-unit Elwell-Parker dynamo are installed. From the dynamo the current is taken to a battery of fifty-six 314 E.P.S. cells, situated in the Falconer's Tower. From the regulating switch-board the cables are taken in cast-iron pipes to the distributing board. The whole of the casings have been cyanised. The carrying out of this large installation has been entrusted to Messrs. Drake and Gorham.

Hastings.—An application will be made by the Corporation for a Provisional Order empowering the Council to supply electricity within the borough for public lighting. The Corporation have also given consent to the Provisional Order of the Hastings Electric Light Company for public and private lighting. The report of the Lighting Committee of the Corporation stated that the estimated cost of machinery for providing 50 arc lamps would be about £5,828, and the annual cost of working the same would be £1,000, as compared with the £1,181 cost of maintaining the gas lamps and electric light lamps at present in use.

Gravesend.—The question of lighting the borough of Gravesend with electricity, and in connection with which it was resolved at a previous meeting of the Town Council to give consent to all the companies applying for Provisional Orders, has been re-opened, it having been ascertained that the giving of consent to the whole would deter any of the companies from moving. Under these circumstances, it was resolved, after considerable discussion, and in direct opposition to the previous decision of the Town Council, that no consent should be given to any of the companies; this decision being attained by eight votes to seven.

The Insulation Resistance of Porcelain Insulators.—In a recent number of the *Centralblatt für Electrotechnik* Herr Schomburg gives the results of some tests made in Berlin of the insulation resistance, in various states of the weather and temperature, of a double bell insulator, measured with an electromotive force of about 100 volts at a height of 7ft. from the roof. The highest resistance obtained was 58,432 megohms; this figure being reached at noon on a warm, sunshiny day in March. About six weeks later the same insulator only showed 180 megohms resistance, the test being taken at 5.30 a.m., when there was a heavy dew. The next day, in the pouring rain, the resistance was 1,051 megohms. On the same day that the

Digitized by Google

resistance of the insulator at noon was 58,432 megohms, at sunrise it was only 630 megohms.

The "Agir" Motor.—The prize of 100 guineas offered some two years ago by our contemporary *Industries* for the electric motor which best fulfilled the conditions then laid down as regards weight, speed, efficiency, &c., has been awarded to Messrs. F. V. Anderson and J. O. Girdlestone, the designers of the "Agir" motor. To decide the prize two 10 horse-power motors were actually built after what were considered the two best designs, and officially tested at the Silvertown Works. The following data are furnished by our contemporary:—

E.H.P. Supplied	Speed of Motor Spindle.	Mechanical horse-power given off motor spindle.
11·81	248	7·31
14·85	285	10·6
12·70	252	9·48

The motor is a two-pole series-wound machine, weighing 985lb., and is designed to work with a current of 150 volts pressure.

Royal Meteorological Society.—At the first meeting of this Society for the present Session, the "Second Report of the Thunderstorm Committee" was read. It was a discussion by Mr. Marriott on the distribution of days of thunderstorms over England and Wales during the 17 years 1871—87. Notices of sheet lightning are included in the term "thunderstorms." The years of greatest frequency were 1880, 1882, 1884, and 1872; and the years of least frequency 1887, 1874, 1879, and 1871. Years of greater or less frequency alternate regularly throughout nearly the whole of the period. The average yearly number of thunderstorms is about 39. The districts with the greatest yearly frequency are the south of England and extreme northern counties: and those with the least yearly frequency are Cheshire, Lancashire, and Yorkshire. The greatest number of thunderstorms occur in July, and the least in February and December.

The Influence of Dielectric Media on Electric Forces.—M. A. Stepanoff has devised the following apparatus to exhibit the modifying influence of a dielectric medium upon the intensity of electric forces. A very light horizontal Zöllner pendulum is arranged in its position of equilibrium with a disc of paper, 4 cm. in diameter, attached to its extremity. On either side of the paper are two metallic discs of the same diameter. The whole system being statically charged, a disc of some dielectric substance is introduced on one side of the paper, which is immediately displaced, showing that the forces of repulsion no longer balance. The same experiment succeeds, though in a lesser degree, when the metallic plates are oppositely charged. The effect is very well seen when ebonite, mica, or varnished-glass discs about 15 cm. thick are employed, but it is necessary that they should be completely discharged by being passed through a flame.

Co-operative Telephones.—At a meeting of a number of users of the telephone, recently held in Manchester, it was decided to send circulars to the commercial community of the city to ascertain the extent of support that would be given to an association on co-operative principles. The circular which has been issued states that estimates have been prepared by a competent engineer, which show that the establishment of an exchange of 1,500 users will require a capital of about £12,000, and will cost yearly for maintenance about £6,000, or, say for each user, about £4 per annum. The cost of private telephones in offices and warehouses would not exceed £1 per annum each, which would give users the great convenience of instruments in every department for a trifling charge. The present exchange charge in Manchester is £20 per annum, and there are about 1,300 renters within a radius of one mile; but at a rental not exceeding £5 per annum, it is believed an exchange of 2,000 to 3,000 renters can be formed.

Canadian Telegraphs.—Mr. Gisborne, Government Superintendent of the Telegraph and Signal Service of Canada, during the past summer completed the land lines upon the North Shore of the Gulf of St. Lawrence, to Point aux Esquimaux, about 660 miles below Quebec. This line is constructed with cedar poles, No. 6 galvanised iron wire, and No. 9 tie wire, purchased from the Whitecross Company, of Warrington, England, Gisborne's porcelain insulators being used. The Director of the Quebec Observatory, who has been determining the correct longitudes and latitudes of various points in the Gulf, speaks very highly of the efficiency of the new line. From Point aux Esquimaux the Canadian Government are about to lay three loop cables next summer to the Straits of Belle Isle, viz., one of 75 knots, to Natashquan, thence by land line, 25 miles, to Kegashka; thence, 114 knots, to Meccatina; and thence, 84 knots, to Greenly Island. This will form one of the connections with the proposed Canada Atlantic Cable Company, a second and third connection being made direct from Greenly Island with the Government systems upon Anticosti, and with the province of Quebec.

Keighley.—At the last meeting of the Town Council the Gas Committee recommended that the Town Clerk be instructed to apply for a Provisional Order. Alderman Brigg, in moving the adoption of the report said that notices had been received from two electric lighting companies. The Committee considered these applications, and they were of opinion that it was very undesirable that an outsider should have powers. With that view the Council declined to accede to the requests of these two companies, and as a result of that refusal the Town Clerk had received a letter from one of them withdrawing their application. The other company had not as yet withdrawn its application, and therefore it was necessary that the Council should put itself into a position of being able if necessary to proceed with the electric lighting for itself. He believed that in the event of the other company withdrawing their application, the Gas Committee would not prosecute their application this session. The Committee had no wish to adopt a policy of doing nothing themselves and refusing to allow anyone else to do anything, but they were rather wishful of obtaining as much information as could be had before starting on such an undertaking as this. The report was adopted.

Electric Light Installation on the "Admiral Nakimoff."—The "Admiral Nakimoff" is the first Russian battle-ship lighted throughout by electricity. The installation was set up by the Jablochkoff Company, and consists of four compound-wound 320-light 65-volt Gramme dynamos, driven by four separate engines. The engines working each pair of dynamos are connected by separate steam pipes to both the main and auxiliary boilers. Each dynamo can be switched on to any circuit at will, and each pair of dynamos can be connected in parallel arc. The mains form three closed double circuits, all connected to the main switch-board. Two of these double circuits supply the gun and main-decks, one pair extending along the port side of the gun deck, descending at the bows to the main-deck thence led aftalong the whole length of the port side of the main-deck, and ascending at the stern to the gun-deck, where the respective conductors join, and thus form each a complete circuit. The second pair of conductors travel along a parallel path, but on the starboard side of the vessel. The third pair of conductors supply the engine-rooms, stoke-holes, and magazines. The corresponding mains of the port and starboard circuit on the gun and main-decks can be connected together at the fore and after part of the ship by means of switchboards, to which they are connected by supplementary conductors. The lights on the fore and after orlop-decks are regulated by auxiliary switchboards, so that they can be fed direct from the dynamos, or, in cases of need, from 150 accumulators on each deck. The advantages claimed for this system of lighting on war-ships are, that the laying of the conductors on the gun and main-decks in an annular path prevents the extinction of any lamp, in the case of a single injury to one of the conductors by an enemy's shell; as the mains will be still connected at the ends to the dynamo, and the circuit will not be broken. By joining the circuits at the fore and aft switchboards, even the total severing of one pair of the conductors leading to the main switchboard would not cause the extinction of any lamp. Moreover, the orlop-decks, where the chief engines of war are situated, being supplied either by accumulators or the dynamos, their illumination can be cut off only by the destruction of the decks themselves.

A COMPARISON BETWEEN THE CONTINENTAL, AMERICAN, AND ENGLISH DYNAMO-ELECTRIC MACHINERY.

BY ALBION T. SNELL.

(Continued from page 6.)

The Miot dynamo and motor, made by the firm of Messrs. Mégy, Echeverria, and Bazan, are also abnormal. This is at once apparent on reference to Fig. 9. A shunt-wound generator and a series motor, constructed on these lines, were used to drive the Pont Roulant in the Machine Gallery. The object of this peculiar distribution of the pole-pieces is not clear. Indeed, this arrangement causes inequality of magnetism in the armature core. This is proved by the fact that two brushes are coupled in parallel between those pairs of poles which are farthest apart. The effect of this is to short-circuit, or render inoperative, that portion of the winding between these brushes, so reducing the output of the machine without any apparent gain. The magnet shapes are costly, and the coils must be hand-wound. Probably as good, if not better, results could have been obtained by a normal four or six-pole machine of the same weight. The cost of construction would probably have been less.

Amongst the American machines shown at Paris, there were several constructions which are not in general practice here. These are usually found in connection with arc dynamos. The enormous practice American engineers have had in this branch

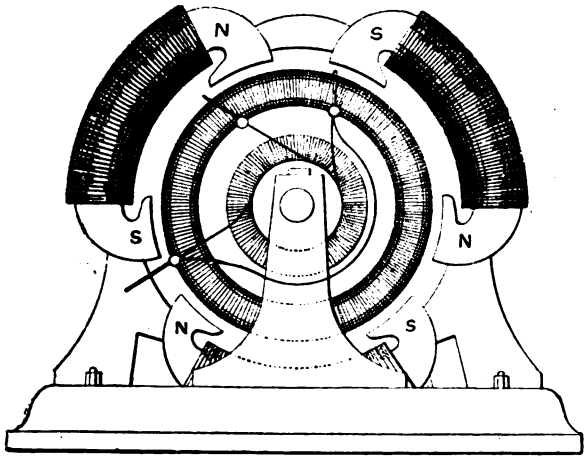

Fig. 9.—The Miot Dynamo.

of lighting has led to a variety of designs based on both open-coil and closed-coil armatures. All of these machines are arranged, I believe, with well-saturated fields and considerable self-induction. The old Brush dynamo still stands in no little favour. The Thomson-Houston dynamo has become so common with us as to excite but little curiosity; yet who can give an intelligible explanation of its wonderful performance? The Sperry arc dynamo is not so well known on our side. This machine has both internal and external pole-pieces, arranged with a cylinder armature with the ordinary Gramme winding. It really is a two-pole machine, the poles close together being of the same sign. A cross-section is shown in Fig. 10. Whether this complicated and apparently wasteful construction is necessary to obtain an equal distribution of E.M.F. in the armature coils appears somewhat doubtful. At any rate, the machine runs well, and regulates quickly, without "hunting" or excessive sparking. The regulation is made by shifting the brushes. These may be rocked through 90deg. till the dynamo ceases to excite. The regulator details are somewhat complicated, and apparently would require a good deal of attention. This form of constant-current regulation is adopted by several other American firms.

On the Continent and in England the same method of regulation is used with success. But the fields are generally the normal two-pole or multipolar type, and the armatures are simply large cylinders with Gramme windings (a few have drum windings). Messrs. Statter and Co. have given a deal of attention to this form of constant-current dynamo with success. I believe no firms, other than the Brush and Thomson-Houston, are building open-coil armatures for arc lighting. It is difficult to form an opinion as to the relative advantages of the open and closed-coil windings. There are not wanting, however, those who think the closed-coil will prove the "fittest" in the struggle for existence. Probably, also, experience alone will show whether the best regulation can be made by the variable lead or the shunted-field method. Since the constant-current systems of transmitting energy are steadily gaining ground for certain classes of work, we may expect considerable alterations in this class of dynamo-electric machinery before long.

So far the comparisons have been chiefly confined to dynamos. I will now refer to some of the motors. In Great Britain and Ireland the use of motors is so limited that few of our engineers have any really extended experience of electrical transmission of power. In the Exhibition, however, within ten hours' run of London, there have been, till recently, several very complete central stations for distributing power, and one or two sufficiently large to convince the most credulous that electrical transmission of power is an accomplished fact. The quantity of energy transmitted is only limited by the usual *commercial* and not *electrical* difficulties. If it would pay to localise 10,000 B.-H.-P. at any spot, it could be done.

The motors best known in England are the Immisch, Elwell-Parker, Crompton, Mather and Platt, &c., and there is no need to do more than refer to them. The Continental and American machines, however, are better known to most of us by repute than actual experience. The Exhibition contained some really

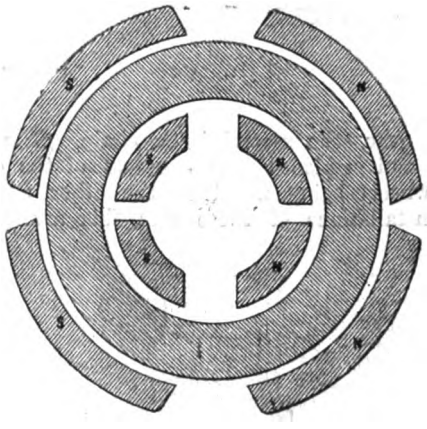

Fig. 10.—Cross-section of Armature and Field-Magnets of Sperry Dynamo.

very fine illustrations of several of these systems. The motor which has attained the greatest success on the Continent is, perhaps, the "Oerlikon." These excellent machines, designed by Mr. A. E. L. Brown, are made with two poles for the smaller types, and with multipolar fields for the larger sizes. The armatures are cylindrical, with Gramme windings. The largest direct-current motor yet built by the firm is, I believe, rated at 300 B.-H.-P. Readers of the technical Press during the past year or two will recollect the notices of several plants installed by the Oerlikon Company. I can only say that the machines at Paris fully answered to the high expectations raised by these descriptions. La Compagnie pour la Transmission de la Force par l'Électricité showed several motors, amongst others a 60 horse-power machine of the Marcel-Deprez double armature type. The transmission is effected at 1,000 volts. I have already referred to this type of machine when used as a generator; the same remarks will apply to the motor with a further objection. If one armature broke down, the second would, most likely, be useless for its share of the load without special gearing. The Compagnie Gramme had an interesting collection of motors. The modern type, so-called, has a vertical single magnet with the yoke cast in the bed-plate. There is nothing very special, however, in any of these smaller exhibits. The machines are all similar to one or other of the designs in common use in Great Britain. Perhaps the most noticeable feature was the number of motors

Digitized by Google

shown. This would seem to suggest that Continental engineers expect an extended use of motors for industrial purposes in the immediate future. Mention has already been made of the curious Miot motor, which ran the overhead traveller in the machine hall. The Julien Electric Tramway Company, of Brussels, showed one of their tramcars and also a motor truck equipped with a single horizontal magnet Gramme motor. The gearing comprises two transmissions. The first is made by toothed gear, the second by a chain. The truck has four wheels and is placed near one end of the car, a pair of rolling wheels being fitted at the other end. In the American installations of these cars this arrangement has been altered. Some of the cars are fitted with two four-wheeled bogies, each equipped with a motor: other cars have only a four-wheeled truck. The workmanship and execution of details seem, generally speaking, not so well carried out as in those motor trucks of American origin. Indeed, as was to be expected, the United States exhibits for the transmission of power show evident signs of large experience. The Sprague motor truck (Fig. 11), familiar to us all by the technical notices, is well worthy of criticism, for there are probably more electric tramcars run on this system than on any other. Hitherto these cars have been chiefly run on the direct system at a difference of potential of about 400 volts. The trucks have four wheels, and each pair is driven by a motor rated at 8 horse-power. The gearing is made in two transmissions, both being cut spur-wheels. The high-speed pinion on the motor shaft is cut on a built-up blank of red vulcanised fibre. This gearing runs almost noiselessly, and is said to wear as well as cast steel. Probably the relatively soft fibre springs sufficiently to always engage two if not three teeth, and hence back-lash, and consequently the wear is reduced to a minimum.

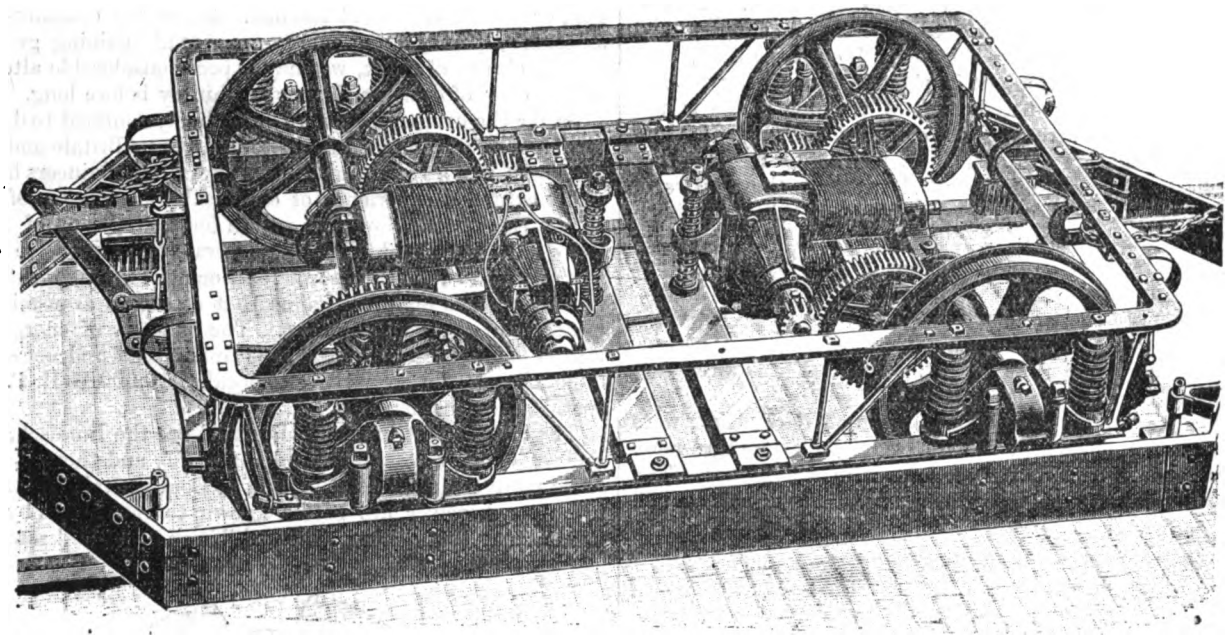

Fig. 11.—Sprague Motor Truck.

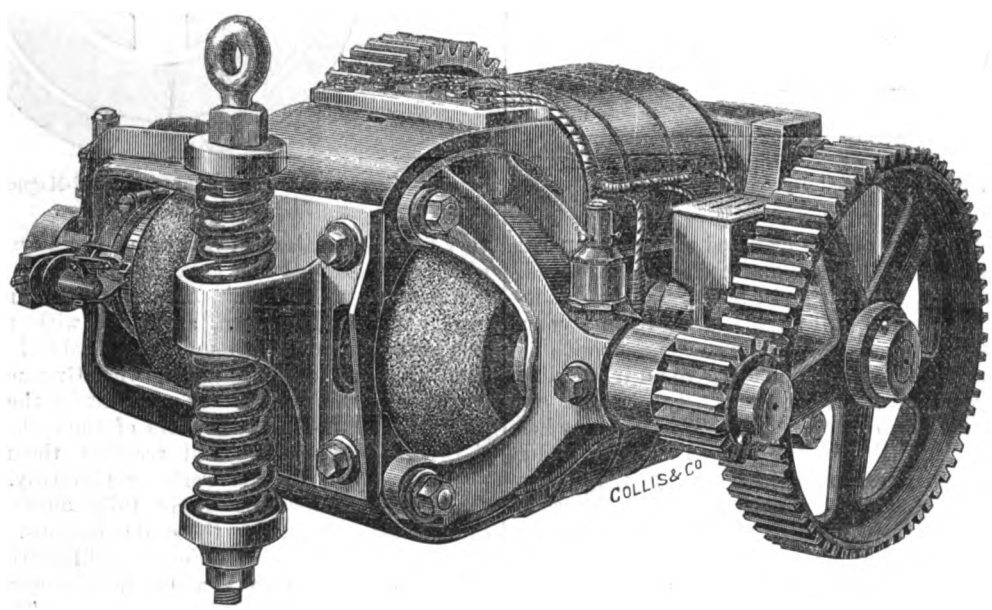

Fig. 12.—Sprague Street-Railway Motor.

The motor (Fig. 12) is of the horizontal single magnet type, with a drum armature. The speed is regulated by altering the coupling of the field windings. The brushes are blocks of ordinary battery carbon, placed in suitable holders, at an angle of about 40deg. to the horizontal (Fig. 13). The direction of motion is controlled by the switch.

There is, of course, room for criticism of most of these details. I have referred at length to the method of starting the motor

Digitized by Google

without resistance in *The Electrician* of August 31, 1888, and November 30, 1888. The advisability of using a drum armature for so high a tension as 400 volts, in such an exposed position as a tram truck, is also open to doubt, and the gearing may be called in question. But there can be no two opinions about the excellence of the workmanship and the thoroughness with which all the details of the design are thought out. The method of insulating the armature wire is novel. The iron core is first coated with a black waterproof varnish, and then covered with indiarubber,

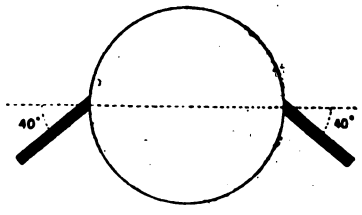

Fig. 13.

which is vulcanised in position. The cotton-covered copper wire is also coated with a varnish said to be completely water-proof. One form of the switch arrangement is as follows:—A circular switch-box, somewhat similar in design to the Julien accumulator switch, is placed under the car flooring between the two axles. This is coupled to the two motors, so that they are both controlled by the same movement. A circular motion, from the position of rest, starts the motors in the one direction or the other, according as the handle is rotated to the right or the left. This main switch is connected by rods to a lever and quadrant at either end of the car, similar to that in use on locomotive valve gears. A forward motion starts the car forward, a backward movement reverses, and the vertical position stops the motors.

The Thomson-Houston Company had a 50 horse-power transmission plant. Both dynamo and motor are designed on the single magnet type, with the yoke cast in the bed (Fig. 14). The armatures are drum wound. The compound

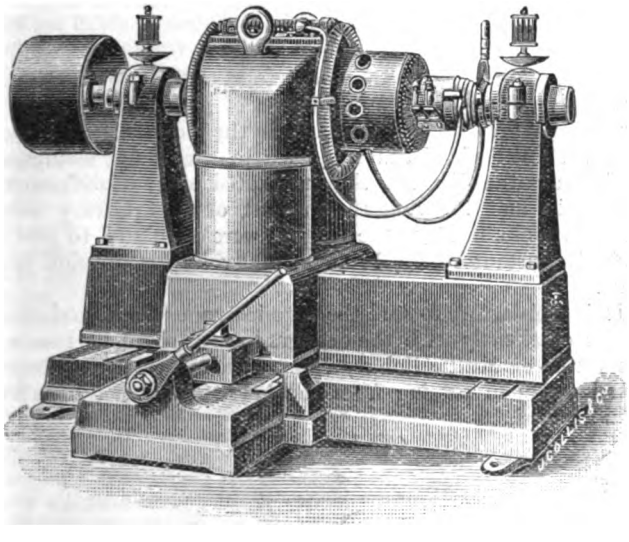

Fig. 14.—Thomson-Houston Dynamo for the Transmission of Power.

coil around the armature is not used in the motor. The E.M.F. at the dynamo is about 500 volts. This company had also some well-designed motor trucks, with gearing similar to the Sprague. The Sperry Company showed an electric coal digger (*Electrician*, July 5, 1889). The motor is a small machine of about 2 horse-power, of the single magnet type. The only special feature is the brush gear. The brushes are of carbon and lie with their points normal to the surface of the commutator. It is worthy of note that the use of battery carbon for motor brushes is steadily gaining ground.

(To be continued.)

SIR WILLIAM THOMSON'S CHAIN OF ELECTROSTATIC VOLTMETERS.

BY ANDREW W. MEIKLE, M.A.

(Continued from page 31.)

The Vertical Scale Voltmeter.

The arrangement of the parts of this instrument will be readily understood from an inspection of the cut given in Fig. 8. The first portion of the condenser is formed by two vertical brass plates of the shape shown in the illustration. These are supported from the back of the metal case by two vulcanite knobs, and are fixed to each other by two cylindrical distance pieces, so as to be accurately parallel. The plates thus, as will be seen, form two quadrant-shaped cells, similar to those of the multicellular, but much larger in size, and having the space between them quite free from obstruction, except at the two corners, where they are bound together by the distance pieces. The centre of the plates has a circular opening through which a brass arm with bearing plates and V guides passes from the back of the case. The movable portion is an aluminium vane, which rests on knife-edges on these bearing plates, and is kept in

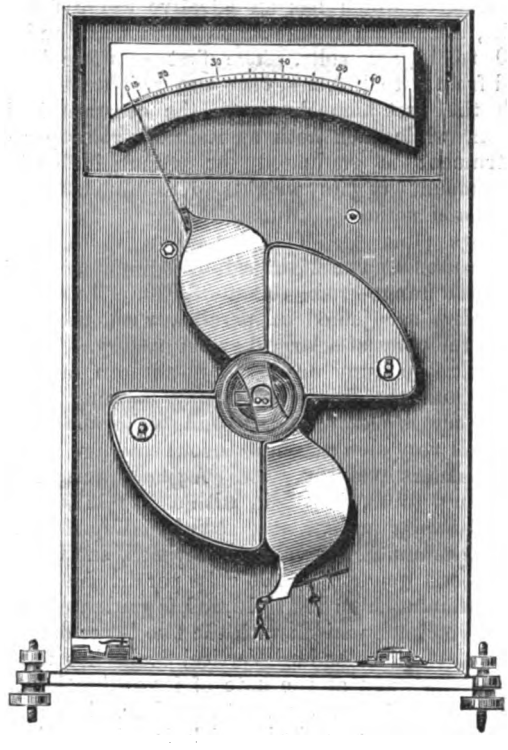

Fig. 8.—The Vertical Scale Voltmeter.

position by the V's, so that it is free to turn in a plane midway between and parallel to the fixed plates. The upper end of the vane carries a pointer, which indicates the deflections on the scale of the instrument, while to the lower extremity is fixed a knife-edge for weights, with its length perpendicular to the plane of the plate. The vane is adjusted to be in a state of neutral equilibrium by two sensibility screws, which turn one on a vertical and the other on a horizontal arm attached to the lower end of the vane. The shape of the vane has been somewhat changed lately, and, as a result, the scale has much larger divisions than in the earlier instruments.

The following improvements have also to be noted, which greatly increase the portability of the instrument. Two small guard-rings, passing over the knife-edges, are attached to the bearing plates, so that the movable plate cannot be displaced so as to make contact with the fixed portions. In order to prevent damage to the pointer the range of motion of the vane is limited by two stop pins fixed into the back of the case. The left-hand stop is divided at half its length into two portions, one of which screws into the other. When

Digitized by Google

the instrument is packed for carriage, the outer half of this stop is passed through a small hole in the top of the vane, and then screwed firmly into its position. When thus packed the vane is lifted from its bearings, and its knife-edges are held in two slots cut in the guard-rings. In this way the instrument is rendered very portable, and easily adjusted when set up for use.

In the two types of the instrument usually made the scale is graduated from 0 to 60, and the divisions represent equal differences of potential—the actual value of the difference per division being dependent upon the particular weight in use at the time. A set of three weights is supplied with each instrument, providing for three grades of measurement in the proportion of 1 : 2 : 4. The constant is 50 volts per division with the smallest weight on, 100 volts per division with the first and second weights on, and 200 volts per division with all three weights on.

Standardising the Vertical Scale Electrostatic Voltmeters.

The Vertical Scale Electrostatic Voltmeters are usually graduated by direct comparison with standard instruments. In addition to the series of Multicellular Voltmeters, three instruments of the vertical type are kept for that purpose, the first of which has an effective range from 250 to 3,000 volts, the second from 400 to 8,000 volts, and the third from 800 to 12,000 volts. The first of these has a scale graduated from 0 to 150, and only two weights are used, such that with the first alone hung on the constant is 10 volts per division, while with both on it is 20 volts per division. This instrument is graduated throughout its entire scale, and the amount of its weights determined by using a Volta pile and series of Multicellulars in the manner described above (Fig. 6). This low-range Vertical Scale, A, can then be used to check the calibration of the next instrument, B, with range from 400 to 8,000. To do this, the two voltmeters are joined in parallel, with their terminals attached to the poles of a large Leyden battery. The first and second weights are hung on A, so that it can measure up to 3,000 volts, and the first weight only is hung on B. The Leyden battery is then charged, and while the potential is allowed to fall very slowly, simultaneous readings are taken on the two voltmeters every 50 volts. A graduation of B is thus obtained from 0 to 60, such that, with a certain weight on, the constant is 50 volts per division, then by using four times this weight the constant is 100 volts per division, and by using four times the second weight it is 200 volts per division. The third standard, with range from 800 to 12,000, is graduated in a similar manner by direct comparison with the two lower ones.

The second of the standard Vertical Scales has now been in use for some time, and at the date of its calibration the chain of Multicellular Voltmeters was not complete. It was therefore graduated by another method, which is still employed as a check on the present system. The calibration of its scale was obtained as follows:—The instrument was joined in parallel with an auxiliary voltmeter, and their terminals attached to the two poles of the Leyden battery mentioned above. The battery was then charged to such a potential that the auxiliary instrument, X, gave a reading at a definite mark on the most sensitive part of its scale, and a weight of convenient amount was hung on the instrument being standardised, Y, so that it gave a deflection of about half its available range. The potential of the Leyden battery was kept constant by observing the indications on X, and the weights on Y were varied so as to satisfy the condition $d \times \sqrt{W} = K$, where d is the point on the scale which it is wished to obtain, W is the weight hung on the knife-edge, and K is a constant. For example, suppose it were agreed to call the point where the indicator stood with the first weight hung on 30, and the amount of the weight were 400 milligrammes, then the division 60 would be obtained by hanging on a weight of 100 milligrammes; while the weight to give the point for division 15 would be 1600, and that for division 20 would be 900 milligrammes. Thus a scale was obtained graduated from 0 to 60, and, as the force of attraction between the movable and fixed plates of the instrument varies as the square of the difference of potential between them, the divisions represent equal differences of potential.

In order to find the proper weight to make this scale read 100 volts per division, a known difference of potential was multiplied by charging a number of condensers in series, and the voltmeter was used to measure the total voltage between the extreme terminals of the condenser pile. This method of multiplying potential was described by Sir William Thomson at the Aberdeen meeting of the British Association. A diagram of the arrangement is shown in Fig. 9. The difference of potential between the terminals TT' of the standard resistance is known as explained above with reference to Fig. 4 by the indications of a standard centi-ampere balance. The condensers, 16 in number, are joined in series and wires brought from their terminals to commutator bars fitted on to a vulcanite disc; a movable arm actuated by a handle and bearing two brushes can be made to revolve round the circumference of the disc so that the brushes are only in connection with two contiguous bars at one time. Wires pass from the terminals TT' to two spring contacts in connection with the revolving brushes. The movable arm is made to revolve very rapidly, and by this means each condenser is charged in the same direction and each has the same difference of potential between its terminals. The difference of potential between the extreme terminals of the series will then be 16 times that between the terminals TT' of the standard resistance. The insulation of the condensers must, of course, be very high to obtain good results by this method, but as an additional check a Multicellular Voltmeter was applied in succession to the terminal of each condenser and the sum of the readings on it was taken as the total difference of potential between the extreme terminals of the series. It was found that the number so obtained

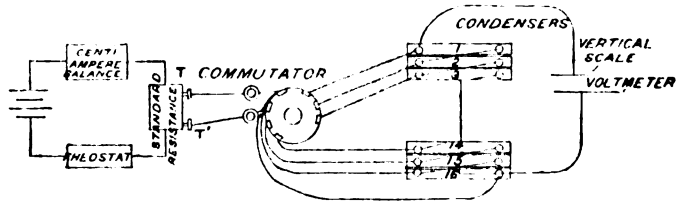

Fig. 9.

differed by about three volts on a total of 2,200 from that got by simply multiplying the difference of potential between the terminals of the standard resistance by the number of condensers. The Vertical Scale Voltmeter joined to the pile of condensers, as shown in the diagram, thus measured a known difference of potential; and knowing the amount of an arbitrary weight hung on its knife-edges, the weights were calculated to give the desired constant of 50, 100, and 200 volts for division of its scale.

It is satisfactory to find that the instrument so standardised agrees excellently with the one graduated by comparison with the series of Multicellulars, a fact which shows that observational errors in passing from the lower to higher ranges have been avoided.

(To be continued.)

SOME PECULIARITIES OF ALTERNATE CURRENTS.*

BY W. E. SUMPNER, D.Sc.

Alternating currents are not by any means new, although it is only lately that they have become of great importance in engineering work. The dynamos first made yielded alternating currents because, as they needed no commutator, they were simpler to construct. They were not adopted, partly because continuous currents were easier to understand and to use, and partly because direct-current dynamos could be made self-exciting. Alternators came to be looked upon as antique types which had yielded place to the more perfect direct-current machines. However, the currents used outside the dynamo, although direct, were, of course,

* Presidential Address to the City Guilds Old Students' Association, November 19, 1889.

Digitized by Google

result of rectifying, by means of a commutator, the alternating currents produced in the armature by its own revolutions. All dynamos, therefore, produce alternating currents in the first instance; and in the same way all motors, before they will work at all, must be fed with alternating currents, whether a commutator is introduced to produce these alternations or not. The action of all machines used for the production of currents depends on the properties of magnetic change discovered by Faraday. The currents induced depend on the rate at which the magnetism varies, and alter in direction as it decreases or diminishes. The magnetism cannot be always changing in the same direction, so that the currents induced must be alternating. Nearly all the useful appliances of magnetism result not so much from magnetism itself as from the alteration of it. This is the case, for instance, in telegraphy and telephony, in which we are always using varying or alternate currents. If I pass an alternate current through one of the coils of this transformer, we hear it singing. The current in the coil induces magnetism in the iron, and this changes in direction every time the current alternates. The magnetism acts on the windings of the coil, causing attractions which vary in amount with the strength of current, and it also causes in the iron itself stresses and strains which alter at every reversal of current. Vibrations are therefore set up, which give rise to a note of a pitch corresponding with the frequency of the current. If due to any irregularities in driving or want of symmetry in the dynamo, the strength or frequency of the current is subject to variation; the note given out by the transformer will indicate this by altering its strength and pitch. The consequence is that the sound given out is very similar to the hum of the engine and dynamo. The transformer acts like a telephone, and, indeed, in principle a telephone is nothing more.

The first difficulty in connection with alternating currents is to settle how to measure them. They are continually varying, and therefore cannot be said to have any value in particular. If I pass the varying current produced by this commutator through an incandescent lamp, you notice that when I turn the handle slowly, the lamp varies in brightness as the strength of the current changes. If, however, I turn the handle quickly, so as to produce twenty or more alternations per second, the lamp lights quite steadily. The strength of the direct current which would make the lamp light equally well is said to be the mean value of the alternating current used. This definition seems simple enough, but it defines the value of a current with reference to its heating effect only. It is soon realised that the importance of an alternating current depends chiefly on its magnetic influence, and not to any great extent on its heating effect. With steady currents the two are proportional, and each therefore is a measure of the other. Partly due to this cause and partly owing to the false notion that the current carries energy along with it, we are liable to confuse the heating effect of a current which represents waste energy with the useful energy of the current which has no necessary connection with it, and in consequence some of the properties of alternating currents seem at first surprising. The efficiency and life of lamps seem to depend merely on the mean heating effect, for, as far as we know, they are the same for direct and alternating currents in spite of the fact that with the latter the maximum value of the current is far in excess of the mean value. With most of the practical applications of alternate currents, however, we have to bear in mind not only the strength of the currents, but also their frequency and magnetic surroundings. The currents and potentials are continually rising and falling in value. They are really waves, and have all the properties of waves.

Now one of the chief peculiarities about waves is that they do not add together in the same way that numbers do. They add together like forces. We all know that if two forces, each of 1lb., are acting on a body, the effect is not the same as that of 2lb., unless the two forces act in the same direction. According to the angle between the forces, the force equivalent to the two may vary from 2lb. to nothing. If two men are pulling at the same rope in order to ring a church bell, it is necessary for them to pull together, or one will tend to stop the bell while the other is trying to ring it. In the same way two waves flowing to the same point will add to each other's effect if their rising and falling occur at the same time; but otherwise they will interfere and diminish each other's effect so that the resultant disturbance may be less than that which either would have caused separately. It does not, therefore, follow that two alternating currents flowing into the same wire will produce a current whose strength is the sum of the strengths of the two components, and, as Lord Rayleigh* has pointed out, if a current branches into two parts, by means of two parallel circuits, it may happen that each of the branch currents is greater than the original current.

I have here the primary and secondary circuits of a Mordey transformer connected in parallel in such a way that if steady currents were flowing the coils would magnetise the iron in the same direction. In the main circuit, and also in each of the branch circuits, a Bernstein lamp is placed. When I close the circuit you notice one lamp is much brighter than the others, and the brightest lamp is in the branch circuit, not in the main. If I now disconnect one of the branch circuits the current diminishes to practically nothing, although the potential on the remaining coil actually increases. Shunting one coil with the other, therefore, not only increases the main current, but also that in the part shunted. These effects, of course, do not occur with steady currents. A somewhat similar experiment is due to Mr. Blakesley. His branch circuits consist, one of a resistance possessing self-induction, and the other of a condenser. By suitably choosing the capacity of the condenser, it is possible to increase the current through the self-induction branch, and make it exceed the current in the main circuit. Mr. Blakesley calls his arrangement a condenser transformer, and it seems to have important practical bearings.

The following experiment is due to Mr. E. W. Smith,* of the Central Institution. It is analogous to Lord Rayleigh's: potentials are dealt with instead of currents. Here is a coil having a fairly large amount of self-induction, in series with an inductionless resistance. Here are two similar lamps of large resistance shunted, one to the inductive, and the other to the non-inductive resistance. I pass the alternating current through the arrangement, and adjust the resistance till the lamps are equally bright. Each lamp now measures the difference of potential of the points to which it is shunted. I now remove the wire which connects the junction of the two lamps with the junction of the inductive and non-inductive portions. You notice that each lamp diminishes in brightness, showing that the whole potential difference is less than the sum of the two halves. By making the shunt connection again, each lamp brightens up, although Mr. Smith's experiments have shown, and theory confirms the fact, that the main current from the dynamo is diminished by so doing. By making the shunt connection, we necessarily diminish the resistance, although the potentials appear to increase and the main current to diminish, quite the opposite of what would occur with steady currents.

I have extended this experiment by forming a Wheatstone's bridge, two opposite arms of which consist of inductive resistances, the remaining arms being non-inductive. To each corner of the bridge I have attached a flexible lead coming to these lamps. The two wires attached to the corners of the bridge connected with the dynamo I have labelled red, and the remaining two, joining the parts of the bridge usually attached to the galvanometer, are labelled white. I connect the red wires to the terminals of the two lamps, the junction of which I connect successively with the white wires, adjusting in each case the corresponding non-inductive resistance till the lamps are equally bright. Each time I make connection with the white wire the lamps brighten as before. From analogy with steady currents we should now expect the bridge to be balanced, since the potential difference between either red and either white wire is the same. This, however, is not at all the case, for if I join the white wires to the extremities of the two lamps, we notice they burn almost as brightly as when joined to the red wires connected directly with the dynamo. Theory indicates that if the impedance of the inductive arm were large compared with its resistance, the potential between the white wires would be exactly equal to the potential between the red ones; and that in any case if the bridge is balanced in the way described, there will be a difference in phase between the two potentials corresponding with a quarter of a period, so that one potential difference will reach its maximum when the other is at zero. Now this is exactly the difference in phase required to drive a Tesla motor. I have here a small anchor ring of iron wound with coils in four quadrants. The coils in opposite quadrants are connected in series, so that a steady current flowing through either pair will cause a north and south pole in the adjacent quadrants. If, now, alternating currents differing in phase by a quarter of a period are sent through the two coils, each pole will move from one quadrant to the next every quarter of a period, so that the polarity will revolve round the ring with the same frequency as that of the alternating current. There is an iron disc free to revolve about the axis of the ring, and when I connect the red wires with one pair of coils and the white wires with the other, you see the disc spins round at a great velocity, and thus forms a Tesla motor. There is, however, this peculiarity about it, that only one alternating current is used. The disadvantage of a Tesla motor is that it requires two alternating currents, fixed in phase with reference to each other, so that it is necessary to have a special dynamo to produce the currents, and also to have at least three leads instead of two. Here, however, is a method of making any alternate current work a Tesla motor. Mr. Blakesley† has, I find, already suggested his condenser transformer for the same purpose. The method I have suggested is not economical, but it can be improved by having the arms of the bridge of high resistance or impedance, and having two opposite quadrants of the Tesla field-magnets wound with many turns of fine wire instead of a few turns of thick wire. Moreover, if con-

Digitized by Google

densers of suitable capacity are substituted for the non-inductive arms of the bridge, the waste will be smaller, and the amplitude of the potential between the white wires will actually be greater than that between the red ones attached to the dynamo. At all events, there seems to be fair ground for supposing that some such arrangement can be found, by means of which a Tesla motor can be economically worked off any alternating current.

Striking effects of interference are obtained by putting a coil, whose impedance is large compared with its resistance, in series with a condenser of suitable capacity. If an alternating current is passed through such an arrangement, and measurements of potential are made with a quadrant electrometer used idiostatically, the potentials at the terminals of the coil or condenser are each found to far exceed the potential at the ends of the combination. Theory indicates that under the most favourable conditions the two former are equal to each other, and the ratio of either to the latter is then approximately equal to the ratio of the impedance of the coil to its resistance when this ratio is fairly large. Thus with the secondary of an induction coil having a resistance of 6000 ohms, and coefficient of self-induction 50 quadrants or secohms, and with a condenser of 0·05 microfarads capacity, calculation shows that the most favourable frequency of current to employ would be 98 periods per second, and that the potentials on the coil and condenser would then be each about five times the potential on the two in series. In the confirmation of this by actual experiment, I have had the advantage of the assistance of Messrs. Monckton, Simon, and Taylor, of the Central Institution. The field-magnets of an alternator were excited with suitable currents, so as to produce at varying speeds of the dynamo an alternating potential of about 30 volts. In the annexed table the results obtained are recorded. The number of periods per second corresponding with the speed of the dynamo is indicated in the first column. The second column gives the ratio of the potential on the induction-coil to that of the dynamo, and, of course, is equal to the square root of the ratio of the corresponding deflections. The third column gives the ratio of the potential on the condenser to that of the dynamo. The last column gives the sum of these two ratios, which, but for interference, would always be unity.

Periods per second.	Potential on coil.	Potential on condenser.	Sum of potentials.
73	1·00	1·93	2·93
82·5	1·84	2·64	4·48
102	4·38	4·14	8·52
116	3·28	2·49	5·77
120	2·91	2·06	4·97

From these numbers it is evident that the potentials on the coil and condenser will be equal when the frequency is less than 102 periods per second, and that the sum of the two potentials will be greater than 8·52 times the potential of the dynamo. When it is considered that the self-induction of the coil, which had an iron core, was measured not with rapidly alternating currents, but with a single impulsive change of current, the agreement between the theory and experiment is quite satisfactory. But although theory so perfectly accounts for the effects, it is nevertheless surprising that a difference of potential can be divided into two parts, each of which is so much greater than itself. Of course, if 20 accumulators are connected up in series with 19 others, and in opposition the potential on the whole is two volts, while those of the parts are 40 and 38 respectively; and this tends to prove, what is practically true, that the alternating potentials are in opposite phase, but the peculiarity with alternating currents is that the potentials of the two parts may be exactly equal, while that of the whole is neither the sum of the two nor the zero difference.

What is really happening in these cases of interference is illustrated by an experiment on pulsations which I am able to perform by means of an ingeniously-contrived commutator kindly lent me by Mr. H. B. Bourne. Alternate bars of the commutator are connected together, and to the two ends of a battery of cells. There are two brushes, one fixed and the other movable, so that as the commutator revolves, one brush may be made to move over the bars more rapidly than the other. Each of these brushes is connected with the middle of the battery through the primary of a transformer. As the commutator revolves, an alternating current comes off from each brush. The period will be the same if the brushes are both fixed, and the phase may be altered by moving one brush with reference to the other. If one brush revolves slowly, the two alternating currents are of slightly different period. The two secondaries of the transformers are connected in series with themselves and with an incandescent lamp. The brightness of the lamp measures the sum of the two currents induced in the secondaries by the alternating currents in the primaries. If the currents coincide in phase, the lamp burns brightly; while if the phase of the currents is opposite, as I can arrange by suitably fixing the movable brush, the lamp is extinguished. If I now revolve the movable brush slowly, the phase of the currents is continually altering, and you see the lamp slowly pulsating in brightness. Although the two alternating currents induced in the secondaries are always of the same strength, yet their sum varies from zero to double the value of each, according to the phase of one with respect to the other.

After all, however, the most extraordinary property of alternating currents is that which has been longest known, viz., their tendency to transfer themselves from one circuit to another with which they have apparently no connection. The appearance of these induced currents is accompanied not by a decrease, but by an increase of the primary current. The primary and secondary currents increase together. The explanation is that the currents are in nearly opposite phase, and one current is neutralising the magnetising effect of the other. The magnetism caused by alternating currents always tends to a minimum, and the currents have to arrange themselves so that their joint magnetising effect may be as small as possible. This tendency is very marked at high speeds, and the compensation is almost perfect. The little magnetism remaining is, however, very important, because of its extremely rapid rate of variation. The induced electromotive forces depend on this rate of variation, and not on the maximum amount of magnetism. Thus, in transformers there is a strong tendency for the primary and secondary currents to be in opposite phase. [This is the explanation of a simple but important experiment due to Mr. Mordey, and the fact was proved by a large number of experiments of Messrs. C. G. Lamb and E. W. Smith made at this college some time ago.*] The strength of the currents in the coils also arrange themselves to be nearly in inverse proportion to the number of turns, for this is the condition that the magnetising effects should be equal. There is also a tendency for the magnetism to alter itself in the simplest way possible, and this is according to the law of sines. The secondary currents, therefore, tend to follow the law of sines because they exactly follow the variations of magnetism. The primary current will also follow the law of sines if the magnetism is proportional to the current, but, if saturation is approached, calculations I have made from experimental data show that the primary current may depart very much from a simple sine wave, as will also be the case if the electromotive force acting on the primary is itself irregular. The tendency of magnetic change to a minimum is exemplified in the action of choking coils and in the heating of iron cores. If an opposite current can be induced in neighbouring circuit or bodies so as to cancel the magnetising effect, the primary current is allowed to flow, but otherwise the reluctance of the magnetism to change suddenly will prevent the current rising to any magnitude. The same tendency occurs within the wire itself, for the adjacent portions of the current tend to flow in opposite directions. The tendency to reverse currents is strongest in the centre of the wire, and consequently the current density is less there than near the surface. The resistance of the conductor is increased by this, and the alteration is very important when the wires are thick and the alternations of the current are very frequent; as, for instance, in the thick-wire circuit of electric welders. Thick leads are, therefore, not well suited to alternating currents; but, on the other hand, they are rarely necessary, for, by means of transformers, large amounts of energy can be efficiently transmitted immense distances by means of inexpensive thin wires.

It is not, however, only in engineering practice that alternate currents have become of great importance. Within the last year or so the theory of electricity has been advanced tremendously by the study of alternating currents. We have seen that with rapid alternations the currents are determined chiefly by the magnetic changes which are going on, and that they arrange themselves as far as possible to neutralise each other's magnetic effect without much apparent regard to the electromotive forces acting, or the resistances in circuit. This tends to show that the most important part of an electric current is not in the wire itself, but in the region outside. It has been by considering the changes going on in the medium outside the wire that Hertz has been able to experimentally prove the existence of effects which have hitherto only had a mathematical basis. If a current is reversed in direction, the lines of force surrounding it are also reversed. Maxwell's theory, however, states that they do not reverse instantly. The lines of force near the wire reverse before the others. There is a certain velocity at which the reversal of the lines travels, and this velocity, according to theory, should be about the same as the velocity of light. That this is actually the case is one of the things which Hertz has lately shown. In order to do so, he has made use of rapidly alternating currents. He has also employed a detector whose great delicacy is due to the principle of resonance, which may be illustrated by an experiment of Prof. Ayrton's,† which I have arranged. An alternating current is passing along this stretched

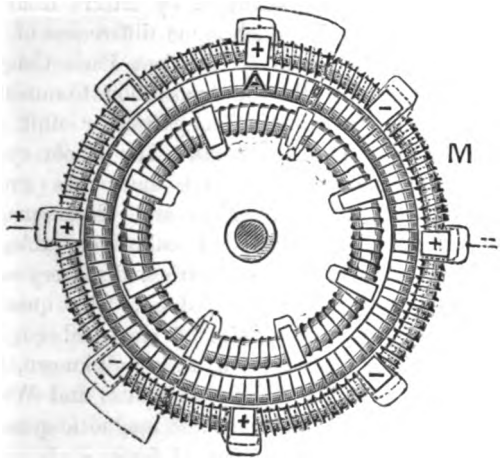
wire. When I hold a magnet near, the wire is pulled aside owing to the mutual action of the current and the magnet's lines of force. Every time the current reverses, the direction of the pull on the wire reverses, so that the wire is put into a state of vibration. The loudness of the sound, however, depends on the length of the stretched portion of the wire. There is one length which will give the best effect, and this happens when the wire is tuned to give out a note of the same pitch as that corresponding with the frequency of the alternating current. The current in any case forces the wire to give out a particular note, but if the wire naturally gives out that note, the sound produced is much greater. The interference of potentials occurring when an induction coil is placed in series with a condenser, is another instance of resonance, for the condition that the potential on the coil should be greatest compared with the whole potential acting on coil and condenser, can also be shown to be the condition that the natural period of oscillatory discharge of the condenser into the coil coincides with the period of the alternating current. It has been by using this principle of resonance that Hertz has been able to detect, in the medium outside the wire, cases of interference with magnetic reversals, exactly similar to those I have shown you with alternating currents and potentials. His work has opened up an endless field of discovery, and these results have been brought about by making use of the peculiarities of alternating currents.

VAN DEPOELE ALTERNATE-CURRENT INDUCTION MOTOR.*

The illustration below shows the principles of the construction of an alternate-current induction motor recently invented by Chas. J. Van Depoele, of Lynn, Mass. The conductors and connections upon the field-magnet system are so arranged that alternate polar extensions will be magnetised by the main supply current flowing through proper conductors. The remaining polar extensions are magnetised by conductors arranged in secondary relation to the



Van Depoele Alternate-Current Induction Motor.

main field-magnet conductors. It will thus be seen that only a single circuit in the machine is supplied with currents from the source, the remaining or other effects being produced by induction. As indicated in the drawing, the armature A is provided with a large number of closed circuits, wound upon a laminated iron core. It is closely enveloped by the polar extensions, which are cut away in the figure for convenience of illustration. Magnetising conductors, M, are wound upon the cores, and when traversed by currents of alternating polarity, the magnetism in the pole-pieces will be reversed. The iron entering into the construction of the cores and pole pieces, being laminated, permits the field-magnets to respond to the reversals in the supply current with the desired degree of rapidity.

Under the influence of an alternating current the action of a field-magnet such as described arranged in inductive proximity to an armature having a number of closed circuits thereon would of itself have little or no effect, since the action of the field-magnets would be merely to create local currents in the closed circuits, which, though polarising the armature core, would accomplish nothing. By the present device, however, the poles created in the armature core by the inductive action of the field-magnets are caused to produce rotation of the armature by a second set of polar extensions arranged to react upon the poles as the energy that created them dies down in the main field-magnets. Such an arrangement takes the form of fixed magnets arranged upon the interior of the armature as indicated. The action of the machine is as follows: A primary phase of current rising in the main field-magnet coils will magnetise the polar extensions, and the lines of force from the pole passing through the armature conductor in proximity thereto will create secondary currents in the armature conductors. These secondary currents will establish definite poles in the armature core, which will be of opposite sign to that of the polar extensions by which they were created. The same phase of primary current by which the armature core was magnetised, as just described, will also produce secondary currents in the secondary field-magnet conductors, and as the primary phase dies in the primary circuit, the secondary currents created thereby will bring the secondary pole-pieces to their maximum magnetic strength. This will occur substantially at the same time as the poles are produced in the armature core by the secondary current, and the secondary pole-pieces being in advance of the primary pole-pieces, the armature will be attracted, and will have a definite and powerful torque, whether in motion or prevented from moving by mechanical means. The effect of the primary pole-pieces upon the core is repeated by the secondary pole-pieces, so that the phases alternating in the pole-pieces each create a current in the armature conductor. This current establishes a pole to be acted upon by the pole-piece in advance.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Elec rical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL UNITS.

Our columns were lately occupied by letters from highly esteemed correspondents, in which some differences of opinion were expressed on the action of the last Paris Congress of Electricians, and of the British Association Committee on electrical standards, in adopting a particular unit of self-induction and calling it a *quadrant*. The whole system of modern electrical nomenclature and units has grown up out of the application of galvanism and electro-magnetism to telegraphy, and particularly to submarine telegraphy; and the enormous rate at which electrical discovery now progresses is, in a very high degree, due to this quantitative measurement which the necessities of electrical engineering called into existence. This system, as is well known, is based on the absolute dynamical system of GAUSS and WEBER, in which the measurement of electrical and magnetic quantities is made to depend on the measurement of force, work, or power, and is, therefore, made ultimately referable to the fundamental standards of mass, length, and time. In building up a logical system of electric units on this absolute system, in terms of the centimetre, gramme, and second, we are first of all met by the difficulty that the absolute electric units are either too large or too small for practical use. The absolute unit of electromotive force, based on the Gaussian definition of a unit magnetic pole, is one hundred million times smaller than the average electromotive force of a Daniell's cell, and the unit of current on the same system is some ten times greater than the currents taken by a 50-volt 16-candle incandescent lamp. The first step in rendering this system convenient for practical use is to multiply or divide the magnitudes of these C.-G.-S. units by powers of 10, and obtain the units which were called by the British Association Committee the *practical units*. We arrive thus at a definition of what ought to be the magnitudes of the electrical units, which are suitable for use. The next step involves us in greater difficulty.

Digitized by Google

These ideal units have to be rendered concrete, and the standards embodied in a material form, or in a definite physical process, to be of practical use. The unit of resistance required in a workshop is not a mere definition of unit, but a piece of wire which possesses the quality of electrical resistance in a known and definite degree. The statement of the manner in which the unit of electric current is to be defined, as depending upon the magnitude of the force between a certain current in a certain conductor and a particular magnetic pole, also defined by its dynamical relation to other similar poles, is a statement which is perfectly devoid of utility to anyone desirous of measuring the current produced by a given dynamo under fixed circumstances. In this matter we find ourselves placed in much the same position as we are in the question of standards of length. A metre may be defined to be the ten-millionth part of the quadrant of a meridian; but we can make no use of this statement until the metre is embodied in a material rod or bar. If, then, it had been at once possible to translate these definitions of what the electrical units ought to be, on the most convenient system, into actual material standards or processes, so perfect, so exact, and so permanent that no delectable deviation from their ideal values ever existed, we should have been at once in possession of a system of electrical units theoretically complete and practically useful. The relations of the various magnitudes to each other would have been, in reality, that required by theory to subsist. Unfortunately, however, this is not the case. The experimental difficulties surrounding the determination in absolute value of the magnitude of various electrical quantities have only been gradually cleared away; and even the permanence of the material standards themselves has had to be the subject of experiment and doubt. We find ourselves, therefore, in the position that the actual standards which must be the means of reference are not the same in value as those ideal standards which are required to be materialised. Hence the practical units, taking this term to mean the convenient multiples or sub-multiples of the absolute units, are not identical with the most highly probable absolute values of the practically used units, or material standards or actual processes. It is evident that as long as this is the case, confusion is created by the use of the term "practical" to describe both the ideal units and their concrete representations. The term practical ought most naturally to be applied to that which is used in practice, and the phrase "practical unit," if it means anything at all, means the unit which is used in practice, and not that which it was intended the unit should represent.

In a Paper read before the British Association at Manchester in 1851, the late Sir CHARLES BRIGHT and Mr. LATIMER CLARK laid the foundations of that system of nomenclature in which the appropriate multiple or sub-multiple of the absolute unit was christened by a short name derived from the surname of some illustrious investigator. Hence the names Ohm, Volt, Farad, now so familiar, were originally each applied to the ideal unit, which is some decimal power of the absolute unit, based on the system which is built up on the Gaussian definition of a magnetic pole, and on the unit of electric current, which is determined by the electro-magnetic quality of the current. In process of time it was found that the standard resistance coils, which were originally constructed by the British Association Committee to be the concrete representation of the ohm, fell short of the ideal magnitude by about 1·3 per cent. Accordingly, these resistances, often called British Association units of resistance, and the countless copies of them which existed, came to be regarded as very imperfect realisations of the ohm. The 1884 Congress of Electricians in Paris decided that a more approximate representation of the ohm would be obtained by accepting as the material standard of resistance the electrical resistance of a column of pure mercury at 0° Cent., having a length of 106 centimetres, and a cross-section of one square millimetre. There are many who now think that this decision is to be regretted, and that the interests of practical science would have been better served by waiting until a better consensus of opinion had been obtained on the absolute value of the British Association unit, and such as would have enabled a standard to be constructed representing with the greatest probability of accuracy the ideal ohm. As it is, neither the British Association unit nor the Paris Congress unit are anything more than arbitrary standards of resistance, approximating in value to that ideal resistance which is called the ohm. Hence have arisen such qualifying phrases as "Legal Ohm," and "British Association Ohm." There is no one, however, we think, who would deny that the term ohm should properly be applied to a unit of resistance which is one thousand million times the absolute unit of resistance on the electro-magnetic system employing the centimetre, gramme, and second, as fundamental units.

We have now, apparently, reached the point when the close attention to phenomena of self-induction is bearing its natural fruit, and rendering necessary quantitative work on this subject. Hence arises a need for a unit of self-induction, and for a name for it. The candidates for the post of honour are apparently the *secohm* and the *quadrant*. The secohm has been first in the field. The quadrant has the weight of authority at its back. Moreover, there seems to be a difference between them. Prof. AYRTON contends, and we think rightly so, that the practically used unit of self-induction must be one which is connected with the practically used unit of resistance and electromotive force by a relation given by the well-known equation for the value of the current flowing at any instant in an inductive circuit under a constant electromotive force. Hence, if we *measure* resistance in so-called legal ohms and electromotive force in corresponding legal volts, the unit of self-induction must be of such a magnitude to correspond with these; and if we understand his letter of October 11 rightly, the secohm is intended to be this unit. We might here remark that it follows, as an obvious consequence, that if anyone measures resistance in British Association units, or old ohms, and electromotive force in the corresponding units, they will be under the logical necessity of employing a unit of self-induction which is not the secohm as employed by its originators. The Paris Congress and the British Association Committee have apparently taken the view that the practical unit of self-induction (in the original sense of the term practical) should be the unit correlated to the true or ideal unit of resistance, viz., to the ohm as it was originally intended to be. There can be no doubt that if the terms Ohm, Volt, Farad, &c., are to signify, as they were intended to do, the practically convenient multiples of the absolute units, the practical unit of self-induction which is to fit in with this system, *and to be named*, must be one which is correlated to the true ohm and true volt, and not to the approximate representation of them which, under the names legal ohm or British Association unit, continue to be used until replaced by standards having a better claim to represent the ideal units. To put it more briefly, if the word ohm is to be taken as signifying an electrical resistance of which the dimensions are 10^9 centimetres per second, and if this is the practical standard of resistance in the original sense of the word practical, then the practical unit of self-induction must be one of which the dimensions are 10^9 centimetres. The practically used unit of self-induction will, however, be one which is correlated to the practically used unit

Digitized by Google

of resistance, be this the legal ohm, British Association unit, or any other. The next question which arises is, whether the Committee have done well in christening this unit by a name which evidently has reference to certain ideas concerning the dimensions of the unit. This is not the place to enter into a discussion on the theory of dimensions. We believe that when further research has enabled us to take the dynamical qualities of the electro-magnetic medium properly into account in forming the fundamental equations, the whole of the present mode of regarding the dimensions of electrical quantities will be modified. Meanwhile, we rather question the wisdom of affixing a dimension-suggesting name to any electrical unit. Is it not rather departing from the original idea that the names of the unit should be simply distinctive sounds abbreviated preferably from the names of men? Nor are we very much in love with "secohm" as a name. We do not call a coulomb a sec-ampere or sec-amp, and the once used term of volt-ampere gave way immediately at the suggestion of the late Sir W. SIEMENS to call it a *watt*. We would have preferred to have seen the matter arranged as follows:—Let a short name, preferably the abbreviation of the cognomen of some illustrious electrician, be affixed to that unit of self-induction which on the present system of measurement has a dimension of 10^9 centimetres. Hence this unit is systematic with, and correlated to, the true ohm, true volt, &c. Then, as in the case of the ohm, prefix the adjective "legal" or "practical" to denote the practically used unit. This is what, we presume, the Congress and Committee have desired to accomplish. The Quadrant is the practical unit, but measurements of self-induction which are made with resistance boxes of legal ohms, and stop-watches giving mean solar seconds, give the result in legal quadrants, and are reduced to centimetres by multiplication by a factor, of which the highly probable value is $\cdot 9977 \times 10^9$.

Whether results of measurements are expressed in secohms or quadrants, it will evidently be necessary for the user of these terms, for some time to come, to define what he means by them. The practical man can base the whole of his electrical measurements on an ohm, an ampere, and a second, and provided we have defined once for all what is *the* standard of actual resistance, and what is *the* actual process by which an ampere is recovered, all the measurements of practical work can be conducted with perfect success and consistency. There are occasions when the necessity for knowing the most highly probable absolute values of the practically used unit arises, but for industrial purposes the most important fact is that, given a unit of resistance defined and distributed in the form of a coil of wire, and given a definition of an ampere in terms of the amount of silver deposited by it under definite circumstances, the whole of the essential practically used units can be recovered by any competent person. We do not think that the measurement of self-induction has become such a frequent workshop operation as to make the selection of a name for its unit an important question; but, meanwhile, two bodies of authority have adopted the term *quadrant*, and it is sufficiently intelligible to be understood, even though there may be, as we have shown, some objections to it. As a matter of fact, whenever measurement of self-induction does become a workshop operation, it will certainly be effected by comparison with a material standard of self-induction, and this will have to be calibrated consistently with the practically used standard of resistance.

Besides the mere question of a name for this unit of self-induction, our correspondence has opened up other matters on which opinions evidently differ, and these we will consider on another occasion

NOTES ON ATMOSPHERIC ELECTRICITY AND THE USE OF SIR WILLIAM THOMSON'S PORTABLE ELECTROMETER.*

BY C. MICHIE SMITH.

At the Aberdeen meeting of the Association, Sir William Thomson communicated a Paper of mine on the general conditions of atmospheric electricity in Madras.† Since then I have continued the observations, and have fully confirmed the conclusions arrived at, that while in Madras, as elsewhere, the most common fine-weather electrification of the air is positive, the normal condition during dry, hot, dust-laden winds is that the air shows a negative potential. To-day I wish to call attention to one or two special observations. In Madras, at certain seasons of the year, we frequently have magnificent displays of sheet lightning, night after night, and I have often made electrometer observations from the roof of the house while these displays were in progress. In some cases an evident effect was produced on the potential of the air, but in general it was found that the electrification was normal. This points to a conclusion which I long ago arrived at, that so-called sheet lightning may be clearly divided into two classes. There is, what all recognise, the reflection of distant lightning seen on the clouds or on the sky, but there is also—and it can easily be distinguished from the former—a series of discharges going on between two neighbouring masses of cloud. These discharges often take the brush form; at other times fine flashes may be seen lighting up the whole mass of the cloud, and at times a large series of discharges, almost parallel and simultaneous, pass betwen the two cloud banks.

Such discharges taking place at a considerable distance do not sensibly affect the electrometer. On the other hand, when the sheet lightning is simply the reflection from distant flashes, the electrometer is usually strongly influenced. I have been able during a violent storm at a distance to draw actual sparks from the wire carrying the burning match. That clouds, or at least masses of mist, vary greatly in potential in different parts I have found by actual measurement. In one case I found on the Neilgherries, at a height of about 7,300 feet, that the mist as it drove past was partly positive and partly negative. The subject of the electrification of mists deserves a much closer study than it has yet received.

When in Japan last June I took a series of electrical observations during the ascent and descent of the active volcano of Asamayama, and though the results are almost purely negative, they may have some interest. I will not trouble the Section with the detailed observations, but the general result was that during the ascent the readings were all positive except one, and varied from + 45½ div. at the lowest point to + 137 at the edge of the crater. The one negative reading was got near the foot of the cinder cone and was − 54 div. It seemed to be due to a mass of cumulus cloud overhead, apparently formed from steam from the crater. At the top the electrification, both at 1·35 p.m. when I reached, and at 3·5 p.m. when I left, was strongly positive. Steam was ascending all the time, but not very vigorously. During the descent the readings were all positive, varying from 147 at the top to 53 near the foot of the cinder cone. On another occasion I took a series of readings in crossing the Wada Pass. These were remarkable from their lowness; all were positive or nil, being 0, 0, + 17, + 5, and at the top (5,300ft.) + 17. I then climbed to the top of a hill some 400ft. higher, standing well clear of the rest of the hills, when the reading was + 100 div. On the descent on the Suwa side readings of + 3, + 17, and + 31 were obtained.

It has been suggested that a few words on the use of the portable electrometer in damp, tropical climates might be valuable. From my own experience of thirteen years I find that the instrument must be treated very differently from what is necessary in this country, and that the observer must be content with much less complete insulation. In the first place the pumice must be charged with a much larger quantity of

* Paper read before the British Association in Section A, Newcastle-on-Tyne, September, 1889.

‡ 1 div. = 4 volts approximately.

Digitized by Google

acid—as much as it will absorb without showing a moist surface. This, of course, involves more frequent drying. I find that about a fortnight is long enough to leave it. The greatest difficulty, however, is in charging the instrument at all. It is almost hopeless to attempt it with the small electrophorus supplied with it, and even when an electrical machine of any kind is used the greatest care is required in drying the charging rod. A ring of ebonite round the charging hole facilitates the operation, and the rod should be removed by means of a piece of warm silk. Recharging will be necessary every three or four days, and a positive charge is best. These remarks may seem superfluous, but I find that the neglect of such simple precautions as I have indicated has been the cause of leading many people to think that the use of the portable electrometer in India is impossible. Perhaps some idea of the difficulties involved will be gathered from the fact that on very few days can a Voss or Wimshurst machine be got to work till it has been thoroughly toasted, and that if it is working when the wind is westerly it instantly ceases to work when the sea-breeze comes on.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"The Lighting of the Centennial International Exhibition, Melbourne, 1888 and 1889."*

BY K. L. MURRAY, C.E.

(Continued from page 40.)

In all efficiency tests but one, Siemens' electro-dynamometers were used to measure the current. For some other tests Ayrton and Perry's meters, of both spring and magnet forms, were used. The values of the readings of these instruments were carefully determined by comparison with the electro-dynamometers. The latter instrument was calibrated by connecting it in series with a battery, an adjustable resistance, and a fixed resistance consisting of a large number of small German silver wires arranged so that any number could be put in parallel. The massive terminals to which the small German silver wires were fastened were connected through a very sensitive reflecting galvanometer and a standard Clark cell. A key was, of course, placed in each circuit. With a given number of German silver wires in parallel, the current through the total circuit was adjusted by means of the variable resistance till the potential difference at the terminals of the German silver wires was equal to the electromotive force of the standard cell. The exact resistance of the German silver wires was immediately measured by the aid of one of Elliot's metre bridges. A small standard resistance was constructed from a piece of the same German silver wire as that used in the fixed resistance. The exact value of this coil was found by comparison with one of Elliot's standard B.A. units. All apparatus to be used was placed in position some time before required, to allow the temperature of all parts to become equal. The temperature was taken by a standard thermometer which had been tested at the Kew Observatory. Two standard cells were used —one by Latimer Clark, Muirhead, and Co., the other made up at the time in accordance with Lord Rayleigh's instructions, whose formula for the variation of the electromotive force of the cell with change of temperature was used. The two cells when tested were found to be almost exactly equal. No difference could be detected when they were compared by the condenser and ballistic galvanometer. But a very small difference did exist, and was shown by the deflection on a sensitive reflecting galvanometer when the cells were connected zinc to zinc, the remaining terminals being connected to the galvanometer. In all calibrations some measurements were taken with each of the standard cells. The results of the calibration tests of the Siemens' electro-dynamometer gave the value of the constant = ·8716. The constant, as given by the maker, was ·87—a difference of less than one-fifth per cent. The same electro-dynamometer, when compared with one of Ayrton and Perry's latest spring ammeters, differed by very little more than ·01 per cent. Two voltmeters were used —one of Ayrton and Perry's spring form, the other of the electro-dynamometer pattern. Both of these instruments were wound with copper wire, and large resistance coils of German silver wire, differentially wound, were used to reduce the potential difference at the terminals of the instrument proper. The voltmeters were calibrated in exactly the same manner as the current meters. They were also checked by measuring the potential difference at the terminals of a known resistance by means of the condenser and ballistic galvanometer. These two methods gave exactly the same results in several tests, and the condenser method was ultimately discontinued, owing to the difficulty of obtaining a place where the ballistic galvanometer could be used without interference from locomotives moving in the vicinity. The dynamometer voltmeter was afterwards compared with one of Ayrton and Perry's spring meters: for 100 volts the difference in their readings did not exceed one-tenth of a volt. The meter-bridge was calibrated by Carey Foster's well-known method. An additional correction had to be made for the heating of the gauge wire by conduction from the binding screws. No special means were previously employed to prevent error from this source, as it was not anticipated that the effect would be appreciable.

The selection of a suitable mechanical dynamometer was not easy. The following conditions were laid down as essential:—1. It must be susceptible of a fair degree of accuracy, and show instantly any variation in the load. 2. It should be of such a form that errors are not likely to arise from the difficulty (owing to the thickness of the belt) of accurately determining the virtual radius of the pulley; and no power should be absorbed between the point at which the pressure is measured and the dynamo spindle. 3. Any springs contained must be so placed that centrifugal force will not introduce uncertain effects on the indications of the instrument. 4. It must be portable and easily fitted up. The first condition simply requires that whatever the principle involved it shall be faithfully executed, and that the moment of inertia and number of moving parts shall be as small as possible. The second condition requires that the power shall be transmitted to the spindle of the dynamo at some fixed distance from its axis of rotation, and that it is the pressure at this point which is shown on the indicating mechanism.

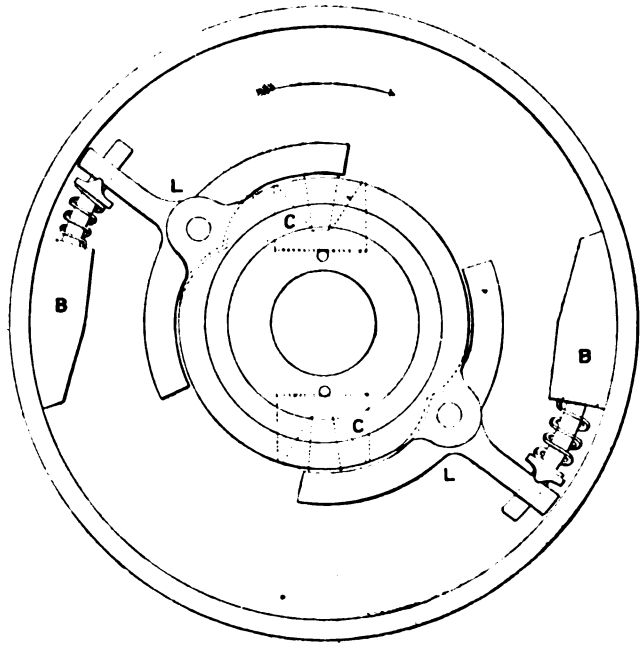

FIG. 1.

The simplest way of fulfilling the above conditions seemed to be to give the dynamometer the form of a pulley to be directly applied to the spindle of the machine tested. It is important that the displacement of any of the parts of the mechanism shall be very small, even though the indicator passes from zero to its maximum reading. A pulley was accordingly constructed the principle of which is as follows:—The energy supplied to the machine is transmitted through a fixed point at a distance intermediate between the axis of the spindle and rim of the pulley. By means of levers and pistons the pressure is transmitted to a fluid filling the chamber in which the piston moves, and by it through a glass tube which lies in the axis of rotation to a spring chamber, the capacity of which varies with the pressure on the enclosed fluid. The pressure on the point through which the energy is transmitted is shown by the displacement of the fluid in the glass tube.

The pulley (*see* Figs. 1 and 2) was made so that the rim R could turn freely on the nave N. Two radial chambers, C, were carefully bored in the nave at the opposite ends of a diameter, and pistons were accurately fitted in them, so that though watertight they could move freely. Two bent levers, L, were hinged at the nave, each being so shaped that when one arm pressed on the centre of the piston, the line passing through this point of contact and the centre of the hinge was at right angles to the radius drawn through the point of contact. At the same time the other arms of the levers

stood in a direction such that the surface of the lever remote from the piston coincided with the radius passing through the centre of the hinge. These arms were of such length that they just cleared the inner surface of the pulley rim. The connection between the rim and nave was made by means of two blocks of iron, B, riveted to the inner surface of the rim in such a position that they would come in contact with the projecting arms of the levers. The point of pressure was rendered definite by the use of knife edges, and any shock was relieved by the interposition of a suitable spring. Two small holes were drilled parallel to the eye of the pulley opening into the cylinders. The indicating apparatus was fixed so that it would coincide with the axis of rotation when the pulley was in use. It consisted of a glass tube, with a carefully fitted ebonite piston which served as a marker. This piston was made about ten diameters long, and had several small grooves turned in it. The glass tube was mounted with a metallic chamber at each end, one being bolted to the pulley nave, the other closed with a circular

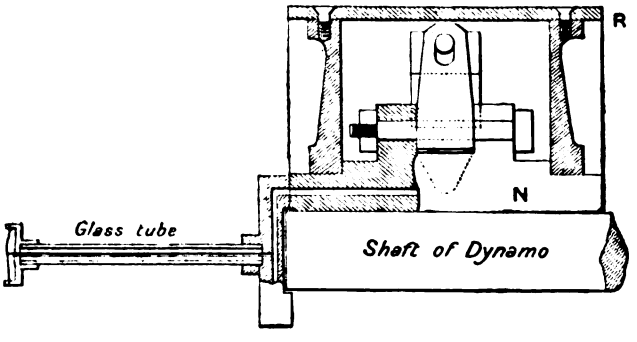

Fig. 2.

corrugated steel spring similar to those used in some steam pressure gauges. The metallic chambers were mechanically connected by an iron tube in which three longitudinal slots were cut to enable the glass tube to be seen. The angular width of each slot was 60deg. The scale was fastened on the inner side of the bars of the iron tube, consequently each time a slot turned towards the eye the glass tube and ebonite piston were seen projected on the scale that was fastened to the opposite bar. When in rapid motion the scale appeared as if drawn round the glass tube, and the end of the black ebonite piston formed a well-defined line from which to read. Every tenth division was marked in red, and the fifties were shown by a bright line on the outer surface of the iron tube. In the pulley used the diameter of the bore in the glass tube was about $\frac{1}{25}$th of that of either piston. Hence, if both pistons were in use, the motion of the ebonite piston would be about 1,250 times as great as that of either of the main pistons. The length of the scale was about 6·5 inches, so that a motion of the main pistons of $\frac{1}{200}$th of an inch would cause the indicator to travel over the whole length of the scale. The pullley was arranged so that one or both pistons could be used. By this means the range of the instrument was doubled. Using one piston and running at 900 revolutions per minute, the maximum reading corresponded to about 30 horse-power, and with both pistons to about double that value. It will be seen that a dynamometer of this form may be constructed to fulfil fairly well the conditions laid down as essential. The sensitiveness is determined by the stiffness of the steel spring and length of glass tube used. In practice a very great degree of sensitiveness is not required, as the variations in the power absorbed were found to exceed two, or at times even three per cent. of the total, whereas one-half per cent. could have been easily read. The ammeter showed fluctuations in the current at least equal in relative magnitude to those shown by this mechanical dynamometer.

To calibrate the dynamometer pulley it was keyed on a fixed horizontal spindle. A long balanced arm was bolted to the rim, and at a distance from the centre of the spindle (measured horizontally) equal to $\frac{20}{2\pi}$ feet a screw was put into the lever. Various weights were suspended from the screw, and the corresponding displacement of the ebonite piston noted. It was found that the displacement was directly proportional to the load; hence the scale could be so divided that the readings would show at a glance the tangential pull of the belt in pounds at any given radius. In the pulley used the constant was calculated for a radius of $\frac{10}{2\pi}$ feet. The reading showed at once the tangential pull at this radius, and multiplying by ten, the number of foot-pounds absorbed per revolution of the armature. It should be noted here that the levers in the pulley were counterbalanced for the centrifugal force of the pistons and fluid below them. The correctness of the balancing was tested by mounting the pulley on a spindle and rotating it rapidly in both directions, first of all having removed the rim. If the balancing were correct a small deflection should be produced, its direction depending on the direction of rotation, and the two deflections should be equal at the same speed of rotation. No error was detected owing to the unequal distribution of the fluid pressure on the circular spring caused by centrifugal force. This fact is not surprising when it is remembered that the effective diameter of the spring was only 1·25 inches, and that the fluid (glycerine) used was light. The dynamometer pulley was placed on the machine which it was desired to test, in the daytime, and fresh glycerine put in. One of the bolts holding the field-magnet core was taken out, and a similar one, but with a hole bored in it to receive the thermometer, put in its place.

The electro-dynamometers were always carefully adjusted for position after all machines were in full work, so that no disturbing effect would be introduced by the action of the current in leads which ran near the testing table. Each reading noted gave the mean position of the indicator for about 15 or 20 seconds in all measurements, whether electrical or mechanical. The speed of the armatures was determined by one of Harding's counters, in all cases a full minute being taken. The constants of all electrical instruments were calculated for the mean temperature of the dynamo room—27° Centigrade. The temperature correction for the dynamometer pulley was not determined, as only the first or last two or three readings were to be used in the results, and the accuracy of these were ensured by taking the zero of the pulley both before and after the machine was run. The intermediate readings were taken only to show if any serious alterations took place in the general working of the machines.

These tests, the results of which are tabulated (*see* Table A), were made primarily to ascertain the commercial efficiency of the various arc machines used. By "commercial efficiency" I mean the ratio of the electrical energy available at the terminals to the actual energy absorbed at the spindle of the machine. It will be seen that the current actually supplied by the majority of the machines was a little below the normal, the machines being professedly designed for a current of 10 amperes. The times of run as shown in the table were not sufficient for the machines to attain their state of steady temperature, though in

Digitized by Google

the majority of cases the temperature reached would be a fair average for ordinary working. The armatures of the machines were interchangeable, so that any given armature cannot be considered a part of any specified machine; it was important, therefore, to ascertain not only the relative value of the different forms of frame, but also of the different armatures in them. It will be seen from the table that the different forms of machine having thin-plate armatures are almost equally efficient, the solid-frame pattern having a slight advantage. The difference, however, between the two forms of machine with thick-plate armatures is still less, and the advantage in favour of the rail pattern. But as only one of the solid-frame machines contained a thick-plate armature the comparison is of little value. For practical purposes it may be said that the commercial efficiency of the two forms of machine, provided the armatures are similar, is the same. Greater alterations in the efficiency of either class may be caused by slight alterations in the conditions of working than the actual difference between the two classes, as shown in the table. The difference in the two types of armatures is very marked. Taking the mean from the two classes of machines, the efficiency of the thin-plate armatures will be found to be about 8·27 per cent. greater than that of the thick-plate armatures. But, unfortunately, the thin-plate armatures were not calculated to withstand the mechanical strains to which they are subjected in ordinary work, so the higher efficiency obtained from them has only a theoretical existence. There is, however, no mechanical reason why the armatures should not be constructed with thin plates, and at the same time be free from the mechanical faults shown to exist in those under review. Indeed, such armatures have been constructed in the Victorian Railways Telegraph workshops, which are quite free from the faults named. One of these has been running for several years without ever giving trouble, and doing excellent work.

(To be continued.)

SOME METHODS OF REGULATING ACCUMULATORS IN ELECTRIC LIGHTING.*

BY GEO. B. PRESCOTT, JUN.

In preparing the following Paper, the limited scope of which is indicated by its title, I have assumed that it is generally conceded that the modern electric accumulator is an apparatus capable of performing a peculiar but useful function in the art of electric lighting as now commercially practised, and that it is free from defects which would render it unsuitable for such application. Indeed, I am sure that every careful observer has noted in the somewhat slow evolution of the accumulator that structural improvement and adaptation to practical requirements which unquestionably show that it has come to stay, and will acknowledge that even as it exists to-day, the accumulator is a factor in electrical industry too important to be ignored by those who take a broad view of the situation. It is not my intention to refer to those numerous successful applications of accumulators to the propulsion of small marine vessels and land vehicles, to car lighting and other minor work where the continuous generation of power from the combustion of fuel would be impracticable; neither can I fully discuss their characteristic actions under working conditions within the limits of this Paper. Although there is reason for believing that some of the early promoters of business enterprises based on the manufacture of electrical accumulators anticipated that the accumulator systems of lighting were destined to compete with and perhaps supersede many direct systems, I believe that the more mature modern idea is that they are, for the present at least, mainly subsidiary to other electric lighting systems. As auxiliaries to many direct systems, accumulators undoubtedly effect a reduction in running expenses, and add an element of reliability. In order to fully appreciate the truth of these statements it is necessary to glance at the conditions commonly existing in ordinary isolated and central station plants as they are operated at the present time. Every one who is familiar with the electric lighting business is acquainted with the vagaries of the load curves during each 24 hours of a central station's run. It is a truism to say that the cost of fuel per horse-power increases inversely as the power plant operates below its normal capacity, and that other operating expenses are, to a considerable extent, fixed independently of the load. In view of these facts it is universally acknowledged that the operation of large power plants of any character during periods of light loads is enormously wasteful. Many have hoped that the supplying of current to small electric motors during the day would remedy the evil in lighting stations, and to some extent the expectation has been realised in manufacturing centres; but even here the unfortunate overlapping of the motor and lamp service still leaves an undesirable margin. Here, then, is a field in which accumulators may perform their special function, not in competition with direct systems, but as supplying the missing feature in the commercially successful operation of 24-hour plants of moderate size. There is no obstacle in the way of applying a sufficient number of accumulators to a plant of the character mentioned, to maintain the light load during the time it would not pay to operate the power plant, and to provide for the charging of the accumulators during the regular running time of the dynamos. Assuming, in illustration of this statement that 10 hours is the ordinary working day, and that the engines of a central lighting station are started at 2 p.m., and are operated until midnight, it is probable, if not certain, that there will be sufficient surplus current for an ample length of time to charge enough accumulators for the service required after the engines cease to revolve, excluding, of course, the period of maximum load, when the dynamos will be taxed to their full capacity in their regular service. Under such conditions the engines could be operated at somewhere near their normal capacity during the whole period of their running time, and the cost of unit power would be a minimum, while only one staff of men will be required. It may be advisable to explain here that although the current available for charging the batteries during the regular running time of the dynamos would vary with the lamp load, this is of no importance, as it is not essential that the batteries should be charged at a uniform rate. In the case of such stations as also supply arc lights, the engines could be started later and operated through the night. Besides reducing the operating expenses of a station during its periods of light load to a greater extent than they increase them at other times, in the event of an accident to the power plant or incandescent dynamos, the accumulators can always be called upon for extra service; while whenever there is an abnormally heavy demand for current they may also be operated in conjunction with the dynamos. But there is still another field in which accumulators may be employed to equal advantage, viz., that of long-distance lighting now so successfully occupied by the alternator-converter system. Indeed, I can only account for the fact that accumulators were not long since more extensively used for this class of lighting, except by the existence of a feeling of scepticism as to their durability, together with their somewhat formidable first cost.

One of the commonest, and perhaps the simplest, applications of accumulators to lighting work is found in their employment in connection with direct isolated plants in factories, office buildings, &c. In illustration of the method of applying accumulators in such cases, we may select as a type of this class of lighting one of those office buildings common in New York and other large cities. This building, we may assume, has already been, or is about to be, wired for 500 16-candle, 100-volt, ½-ampere lamps on the multiple arc plan, and is to be provided with a 125-volt, 200-ampere dynamo; it being calculated that more than 400 lamps will rarely be lighted simultaneously. We are not specially concerned with the power plant, and will simply assume that it is of ample capacity, it being remembered that such buildings are usually steam heated, and, therefore, offer favourable conditions for the operation of a plant of the character under consideration. Now, it can be deduced from experience that during the day, from, say, 9 o'clock in the morning until about sunset, only a limited number of lights will be burned in certain dark corners of the building, and that as twilight and darkness come on the load will gradually increase, reaching a maximum at a certain hour depending upon the season; subsequently the load will decrease, finally reaching a minimum after the janitor and his assistants have finished their cleaning operations, which load will probably be maintained for the remainder of the 24 hours. It is evident that a direct plant operating under such conditions would necessitate the employment of two forces of men, either one or two in each, and would, moreover, be running under exceedingly uneconomical conditions for a large part of the time. Let us now consider in what manner accumulators may be added to this plant in order that it may supply the variable load for 24 hours daily, while at the same time dispensing with the services of one staff of men and reduce the running time of the engine to eight hours. It has been shown in a general way how the load varies during 24 hours; but, in order to ascertain the capacity of the accumulators required, it will be necessary to assume, though only approximately, somewhat more precise figures. Say that the load is as follows:—

From 9 p.m. to 9 a.m.,	20 lamps	= 120	ampere-hours,
„ 9 a.m. to 4 p.m.,	200 „	= 700	„
„ 4 p.m. to 6 p.m.,	400 „	= 400	„
„ 6 p.m. to 9 p.m.,	50 „	= 75	„

An inspection of the above schedule shows that for 12 hours out of the 24 only 20 lamps, or 10 amperes, are used, while for three hours more only 50 lamps, or 25 amperes, are required; and a simple calculation proves that a set of accumulators having a capacity of 200 ampere-hours will be amply sufficient to maintain the light lamp load for 14 hours out of the 24. If the dynamo is started at 8 a.m. and operated until 6 p.m., while maintaining the required number

* Paper read before the American Institute of Electrical Engineers, New York, October 29, 1889.

Digitized by Google

of lamps during that period, it will still have surplus current for charging the battery as follows :—

From 8 a.m. to 9 a.m., 190 amperes for 1 hour,
„ 9 a.m. to 4 p.m., 100 „ 7 hours,

or 890 ampere-hours, an available capacity vastly in excess of the requirements. Now, if during the eight hours in which the dynamo is operating the accumulators are charged at the rate of 30 amperes, in that period they will receive a total charge of 240 ampere-hours. According to the schedule, the maximum output required from the battery will be 185 ampere-hours, whence it follows that the charge received by it is more than ample, even after making the customary allowance of 20 per cent. for loss by conversion ; and the desired result has been accomplished.

We have now to consider the details pertaining to the practical arrangements of such an installation. According to the stipulated schedule, after the dynamo ceases to run at 6 p.m., the battery alone must supply 25 amperes for three hours, and thereafter 10 amperes for 11 hours, or a total output of 185 ampere-hours. One series of 50 cells, having, say, a normal capacity of 30 amperes for eight hours, will satisfy these requirements, and will be well within the nominal rating of ordinary commercial cells. Assuming that these 50 cells, connected in series, have been suitably placed on insulated shelving at any convenient distance from the dynamo, they may be electrically connected with the latter and with the lamp circuit, so that they will supply current to the lamp circuits in exactly the same manner as would two dynamos connected in parallel. This method does not, in fact, satisfactorily permit of that splitting of the dynamo current between the lamps and battery which was incidentally referred to. More than this, it fails to provide a means of compensating for that rise and fall of the potential of the battery during charge and discharge which has been mentioned. How, then, will it be possible to employ the higher pressure demanded by the battery and at the same time supply current to a number of lower voltage lamps without raising their candle-power above normal ? The answer is easily given, for it is only necessary to insert a suitable resistance in the main between the dynamo and lamp circuits in order to accomplish the desired

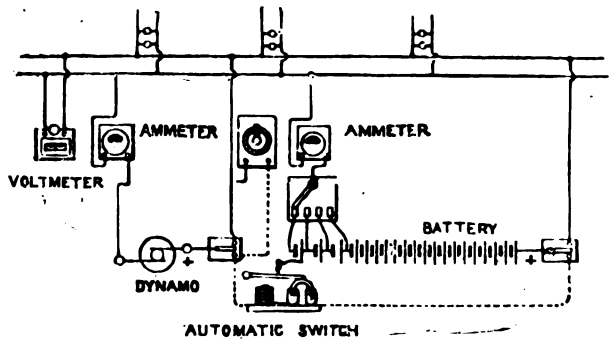

FIG. 1

result. Such a resistance, usually called a "pressure equaliser," should be made of wire sufficiently large to safely carry the current for the greatest number of lamps likely to be required at the time when the dynamo which supplies them is to be simultaneously called upon to charge the battery, and should be made conveniently adjustable, as the fall of potential through it varies with the current. The method of regulating the working potential of the battery is equally simple, for it merely consists in adding to, or subtracting from, the number of active cells in circuit. This is accomplished by means of a multiple-point switch, called a cell-regulating switch, which is so constructed that, in the act of shifting the cells in and out of circuit, it neither interrupts the circuit nor short-circuits the cells.

The method of employing the pressure equaliser and cell-regulating switch is shown in Fig. 1. The function of the automatic break switch is merely to interrupt the charging current, in the event of the potential of the dynamo becoming so much reduced from any cause as to allow the battery to overcome it, and perhaps reverse its polarity. This switch, a practical form of which is shown in Fig. 2, consists of a simple electro-magnet with a weighted armature lever carrying at one end a '∩-shaped bent wire dipping into mercury cups. The charging current passes through this magnet and from one mercury cup to the other through the bent wire. When the current becomes greatly reduced to any predetermined extent, gravity overpowers the attractive force of the magnet, its armature is released, and the bent wire being drawn out of the mercury cups, the circuit is broken. While the method of installing a single series of accumulators in connection with an isolated plant, as described and illustrated in Fig. 1, fulfills most of the conditions required in small plants operating a single dynamo, in larger plants of a similar type, using two or more dynamos, several series of the largest cells may be required. Although such an installation would consist mainly of an amplification of the system already described, still there exists a new difficulty not met with in that system. This arises from the fact already mentioned, that when several series of cells are charged in parallel, any essential difference in the amount of the residual charge in the several series results in their allowing different amounts of current to flow through them, although all of the series are charged at the same potential. The remedy for this undesirable result is of the same character as that employed to prevent excessive pressure on the lamp circuits, when the dynamo which supplies them with current is at the same time used to charge accumulators. In circuit with each series of cells is placed a small adjustable resistance coil, called a current equaliser. It is composed of wire large enough to carry the maximum current of a single series of cells, and usually has a resistance of from 3-10 to 6-10 of an ohm. Each series of cells is also provided with an ammeter, and upon the commencement of a charge the current equalisers are so adjusted that each ammeter shows the same amount of current to be passing through each series. In order to avoid as much as possible any loss of energy in the current equalisers, they are all turned to the no-resistance point at the start, and resistance is then only inserted in such series as may be taking more current than others. It may be mentioned that both the pressure and current equalisers may be made to operate automatically by the application of a potential magnet to the former and of a current magnet to the latter, together with a simple but somewhat expensive train of gears to move their levers. This is found to be wholly unnecessary in practice, however, as an engineer is usually in constant charge of such a plant, while the dynamos are running, and he can easily devote the little time necessary to the infrequent regulation required.

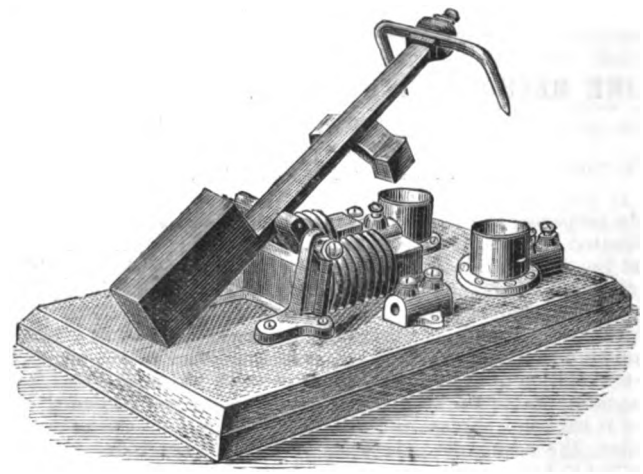

FIG. 2.

It was mentioned in the early part of this Paper that it was possible to injure accumulators either by over discharging them or working them at too high a rate. It is assumed that in the larger plants, there will be such supervision available under ordinary working conditions that occurrences of this kind will be avoided ; but a simple device for preventing such abuse of the cells in smaller plants, where such supervision is not always convenient, has been devised. It is called an overload and overdischarge switch, and its operation is based on the fact that when a series of cells is overdischarged their potential falls below a minimum value, and that when they are worked above their normal rate the current exceeds a maximum value. The apparatus consists essentially of a pressure magnet connected to the terminals of the battery, and of a current magnet in series with the battery. When the potential of the battery falls below a minimum value, the armature of the potential magnet is released and throws an artificial resistance into the battery circuit, and thus reduces the current ; and similarly, when the current exceeds a maximum value, the armature of the current magnet is attracted and performs a similar function. With the object of reducing the cost of the regulating apparatus whenever both the combined overload and overdischarge switch and the current equaliser are to be used with the same series of cells, the switch portion of the equaliser may be mounted on the resistance frame, and thus a single resistance coil be made to do service for both instruments.

In applying accumulators to plants operated on the three-wire system, a simple extension of the method already described is adopted, except in the case of small stations requiring only one series of accumulators, and where the working circuits can be multiplied during the light load, so that the ordinary method will

Digitized by Google

suffice. In larger plants the batteries are installed in pairs, each series having the same apparatus as before; and as this has already been fully explained, it will only be necessary to add that in adapting two series of cells to the three-wire system, the two batteries are connected in series in the same manner that the dynamos are connected. The general plan of this arrangement is shown in Fig. 3, from which unimportant details have been omitted. At the top of this diagram the three horizontal lines M (+), M (±), and M (−) represent the omnibus wires in the dynamo room, from which the feeders, L, are led. The three vertical lines O (+), O (±), and O (−), are extensions to the omnibus wires to which the dynamos are directly connected in the usual manner when the levers of the switches S_1 are on their upper contacts. The batteries are also connected with the omnibus wires in a similar way, so that when the switches S_2 are closed on their lower contacts the batteries will also discharge into the lamp circuits in parallel with the dynamos. Now if the switches S_1 are turned to their lower contacts, and the switches S_2 to their upper contacts, the current from the dynamos will divide at the switches S_1, part going into the lamp circuits, and part through the batteries, which thus receive a charge. As in the multiple arc system, the potential of the dynamos being assumed to be raised above the normal to meet the requirements of the batteries in order to suitably reduce the pressure on the lamp circuits, it is only necessary to adjust the resistance of the pressure equaliser P E. In central stations, where the feeders are already provided with pressure equalisers, the connections are still more simple, for the batteries are merely connected to the omnibus wires, while all other connections of the ordinary three-wire station are unchanged. In such cases the increased pressure at which the dynamos are operated during the time the batteries are charging is

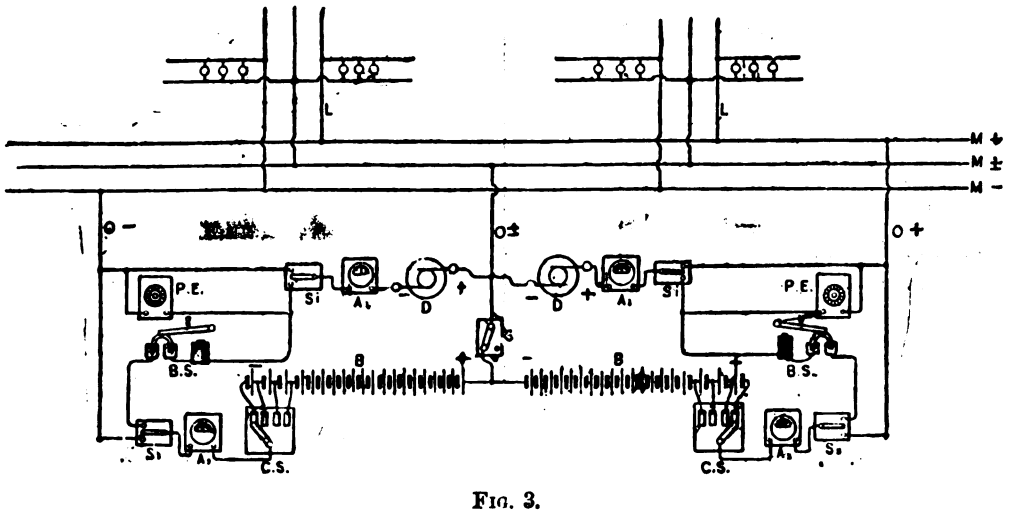

FIG. 3.

reduced at the lamps to the proper point by the usual adjustment of the feeder or pressure equalisers. During the charging period all regulation of the accumulators may be dispensed with by opening the switch S_1, when both batteries will be connected in a single series to the full pressure of both dynamos. In addition to the apparatus shown in the diagram each series of cells is provided with a double plug switch and sockets suitably disposed, by means of which the relative positions of the batteries on the two sides of the system may be changed by simply transposing the plugs from one socket to the other. The object of this arrangement is to provide means for compensating for the unequal discharge of the batteries when the two sides of the lamp system are unbalanced; and the transposition is never made oftener than once each day. In all other respects the manipulation of accumulators when applied to three-wire systems is practically the same as when they are operated on the multiple arc plan. To increase the accumulator capacity of three-wire stations, double batteries are added in parallel to the first set, just as additional dynamos would be.

Regulating cells in each series often become charged sooner than the remainder of the cells, and require to be removed from the circuit before the others. This operation, of course, calls for some labour; and, little as it is, it would still be desirable to have the number of cells in a series remain fixed both during charge and discharge. By the use of what are called counter electromotive force cells, this result may be effected, and at the same time the pressure equaliser be dispensed with. These very simple cells are made, like an ordinary Planté accumulator, of plain sheets of an inoxidisable lead alloy and without active material. When a current is passed through them they act as gas voltameters, and while they instantly oppose a counter electromotive force of about two volts, they are incapable of producing a current of any appreciable amount of duration on account of their inoxidisable property. The use of counter electromotive force cells in place of equalisers is advantageous in several ways, for not only may their internal resistance be made so small as to be practically negligible, but their counter electromotive force is as effectual in reducing excessive pressure as a dead wire resistance, while possessing the unequalled advantage that the fall in potential of the current passing through them is unaffected by any variation in the strength of such current. It is to be noted that by means of the above method, the number of cells in the battery proper is fixed and unalterable during both the charge and discharge, and that whenever the dynamo is supplying current to the lamps, its surplus current is always available for charging the battery; moreover, only one adjustment of the counter E.M.F. regulating cells opposed to the lamp current will be required. It is obvious that counter E.M.F. cells may be substituted with equal effectiveness for the equalisers and regulating cells employed in all of the previously-described systems, and it seems unnecessary to go into any further particulars in order to illustrate the practicability of such systems when properly installed and operated.

We have now to consider another branch of the electric lighting business, in which accumulators also claim a share of attention, viz., the supplying of current to lamps located at a considerable distance from the source of power. The first method to be considered is known as the half-direct plan, in which one or more series of cells are installed in any number of sub-stations conveniently located near centres of lamp consumption. The charging station may be situated wherever economy dictates, without any special reference to the location of the batteries, for although the expense of the charging wire and the cost of the energy wasted in it cannot be neglected, both these factors must be offset by the saving effected from locating the power station in the most desirable situation. This half-direct system is so called because during the period of maximum load half the current is supplied by the charging dynamo, and half by the batteries. At other times the dynamo may be simultaneously charging the batteries and supplying lamps, or the battery alone may be in operation. Each sub-battery station is, in fact, a small central station by itself, and it may contain one or several series of cells, the number, of course, depending upon the amount of lighting to be done in its vicinity. A common charging main, like an arc light circuit, passes through each sub-station, and each battery may be inserted in the main or withdrawn from it at will, exactly as arc lamps are cut in and out of circuit. The charging dynamo is usually of high voltage and of moderate current capacity. Machines of 500 volts and 15 amperes to 1,200 volts and 40 amperes may be employed in small stations, while in larger ones the latter machines and their circuits may be multiplied. For charging purposes shunt-wound dynamos are preferable on account of their non-reversibility, but even series and compound-wound machines may be used if suitable precautions are taken. The arrangement of the accumulators and regulating apparatus in each sub-station on the half-direct system is essentially the same as the method adopted in the last described multiple arc system. The switch which is employed to throw the batteries into and out of the charging circuit is of the snap action type, and is sometimes called a consumer's switch. It maintains the integrity of the charging circuit when the batteries are removed from it, and is provided with a spark coil which prevents the opening of the charging line and the consequent formation of the injurious arc which results on the interruption of high potential circuits. By applying the polarised magnet principle

Digitized by Google

to this switch it can be made to operate automatically from the central station through a momentary reversal of the charging current, a principle which has already been applied.

While the method just described of locating the batteries in sub-stations near the lamps to be supplied reduces the resistance of the supply wires to such an extent that the variation of potential with changes in current strength is unimportant compared with what it would be were all the lamps operated from one central point, under ordinary conditions; still a similar variation does occur from a different cause. We have already seen that the potential of a battery is higher while it is being charged than at other times, and that the greater the charging current the higher the potential of the battery becomes. It is evident that if charging commences when only a very few lamps are burning in a given battery only a small part of the charging current will be required by the lamps, while the greater part will pass through the battery. This will raise the potential of the battery considerably, and as the lamp mains are permanently connected to its terminals, the lamps will receive an excessive pressure. As the number of lamps increases, however, more of the charging current will pass to them and less through the battery, the potential of which thus becomes gradually reduced until it reaches a minimum, when the number of lamps burning becomes so great that the whole output from both the dynamo and battery is required to maintain them. The variation is in the opposite direction, of course, when the lights are diminishing in number. It is evident from the preceding facts that during the period when the charging dynamo is running and the lamp loads are varying some regulation of the pressure at the lamps mains at each sub-station is required. This regulation is automatically effected by means of the apparatus shown in Fig. 4, in which a solenoid magnet, A R, and a polarised magnet, P M, are inserted in the battery circuit. The operation of the apparatus in this sub-station will be as follows:—Assuming the charging dynamo to be delivering

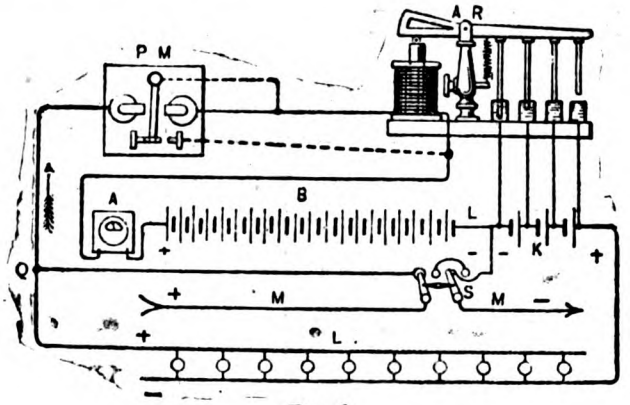

FIG. 4.

a current through the charging main, M, and that the consumer's switch is in the position shown in the diagram, the charging current will pass from M (+) to the point Q, where it will divide, part going through the lamps and the opposed counter electromotive force cells, K, to the point L, and thence to the line again, the remaining part of the current passing from point Q through the magnets, P M and A R, and out through the battery to point L and line. When the current is flowing in the direction of the arrow, as in the case just cited, the armature of the polarised magnet is moved to its left-hand contact, as shown, and the plunger of the solenoid magnet is more or less drawn down, according to the strength of the current. This action of the solenoid magnet causes one or more counter electromotive force cells to be inserted in the lamp circuit in such a way as to oppose their electromotive force to that of the charging current, while the full pressure of this current is available at the battery terminals. If now the number of lamps is increased to such an extent that not only all of the charging current passes through them, but also that more or less current from the battery joins in parallel with it, then the current from the battery will traverse the polarised magnet in the opposite direction from that previously taken by the charging current, and its armature will be moved against its right-hand contact, thus short-circuiting the solenoid magnet and the counter electromotive force cells, as indicated by the broken line. For, as the sketch shows, the lever of the solenoid magnet is so balanced that when no current is traversing the magnet, its metallic contact rods all dip into their respective mercury cups, and so shunt around the counter electromotive force cells with which the latter are in electrical connection. When the lamp load becomes reduced, and the charging current is discontinued either by the stoppage of the dynamo or by its being shunted post that particular battery by a movement of the switches to the right, the battery alone works into the lamp circuit, and the counter electromotive force cells are short-circuited.

While the automatic regulator just described, when applied to the half-direct system, maintains the pressure at the lamps sufficiently uniform for practical purposes, whether the charging dynamo is operating or not, and although the proximity of the battery to the lamps it supplies prevents undue variation of potential when the load changes, yet a perfectly automatic method of maintaining a constant potential at the lamp circuits, even where the resistance of the leads is great, would be generally useful. Such a method is illustrated in Fig. 5, in which the battery, counter electromotive force cells, lamps and charging circuits, occupy the same relative positions as before. The solenoid magnet of the regulator is no longer in series with the battery, however, and is, in fact, entirely disconnected from it, while the polarised magnet is replaced by a second solenoid magnet, P M, wound to high resistance. The armature lever of this second solenoid is so mounted that when its core is attracted or released this lever moves over a series of contact strips which are insulated from each other. Connected with these contact strips are coils of wire of suitable resistance, the whole constituting a simple rheostat, more or less of the wire of which is included in a local circuit, according to the position of the lever, which acts as a movable contact. The solenoid magnet of the regulator, A R, and one or two cells of accumulators are also included in the local circuit referred to, the strength of the current flowing in this circuit depending upon the amount of resistance inserted by the movement of the lever of the pressure magnet, P M. The latter magnet is connected directly with the lamp mains at a point of average potential, and as this potential rises and falls, the current flowing through this magnet varies correspondingly, causing a similar variation in the current in the local circuit. Thus an increase of pressure at the lamps indirectly causes the armature of the regulating magnet, A R, to be attracted, and this in turn opposes one or more counter electromotive force cells in the lamp circuit until the pressure again becomes normal. If the pressure at the

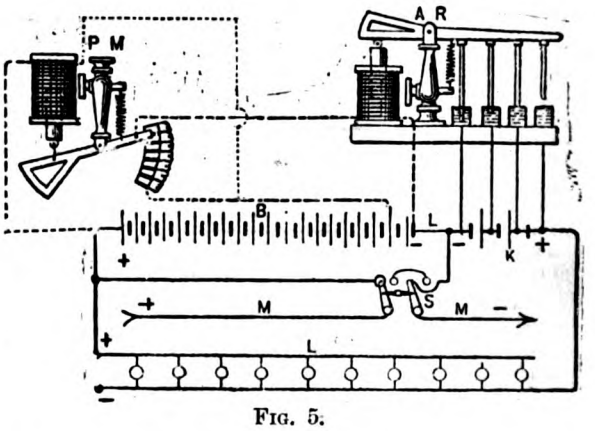

FIG. 5.

lamps falls below normal, the regulator acts in the reverse way, cutting out the counter electromotive force cells until the normal pressure is again restored. If in connection with this method the polarised consumer's switch, previously mentioned, is substituted at S, the operation of such a sub-station will be entirely automatic.

It is proper to mention that the pressure magnet must be very sensitive, and requires a delicate adjustment, besides being somewhat costly on account of the excellence of the workmanship required. Although I have only seen the instrument used in an experimental way, its practical application to similar purposes has given satisfactory results. Under certain circumstances—as, for example, when a lighting station is worked to its full capacity at night, but during the day time has ample surplus power, the all-accumulator system may often be applied to increase the capacity of such a station with satisfactory results. In such cases the sub-stations of accumulators are located at distant points in the usual way, the cells being charged during the day and discharged on the lamp circuits at night while the power plant is doing its regular work. The arrangement of the accumulators and regulating apparatus in the sub-stations of the all-accumulator system is practically the same as when the half-direct system is employed, except that a single transfer switch, which transfers the battery from the lamp circuit to the charging circuit, and *vice versâ*, is used instead of the consumer's switch.

There are, of course, numerous other ways of utilising accumulators in central station supply systems—such, for example, as the double battery method now operated in England by the Electrical Power Storage Company, in which the dynamos are kept running for 24 hours daily, duplicate sets of accumulators being alternately inserted in the charging and supply circuits at uniform intervals of time by an automatic mechanical device. But I have limited this Paper to a description of some of the simpler methods of accumu-

Electromotive force of each cell is about 2 volts.

later regulation which may be readily adapted to ordinary lighting plants, and, in concluding, can only hope that I have succeeded, to some extent at least, in showing that when so applied in an intelligent manner accumulators do occupy a useful place in the industry of electric lighting.

Through the courtesy of the Electrical Accumulator Company I am enabled to present to the Institute this evening a list of a new line of standard accumulators recently brought out by that company.

THE PHYSICAL SOCIETY.

At the meeting of the Society, held on the 15th inst., Mr. J. Enright resumed the performance of some experiments begun at the last meeting, exemplifying

"Electrification due to the Contact of Gases with Liquids."

The author has been making experiments for some time past on the electrical phenomena accompanying chemical action. He finds that when a vessel in which chemical action is going on is insulated and put in connection with a delicate electrometer, electrification can generally be observed when a gas is given off, but not otherwise. The sign of the charge given to the vessel depends, as would be expected, on the liquid employed and on the gas given off, and the author adopts the natural explanation that the effect is due to contact between the liquid and the gas.

The first experiment exhibited to the Society consisted in dissolving zinc in hydrochloric acid in a vessel in connection with a quadrant electrometer, and the author stated that as the proportion of chloride of zinc in the solution gradually increased, the deflection of the electrometer gradually diminished to zero, and ultimately changed its sign.

Hydrogen gas, generated in the same manner, was then allowed to escape into a metallic vessel, suspended with its mouth downwards over the escaping gas, and connected with the electrometer, and it was found that the charge given to the suspended vessel by the escaping hydrogen was opposite in sign to that of the generating vessel in the preceding experiment.

The author stated that when the hydrogen was allowed to escape into a glass vessel the electrification given to the vessel was of the same sign as that of the generator, from which he concluded that the arrangement acted like a condenser. This idea he confirmed in a very ingenious manner by dissolving soap in the acid, so that a mass of small bubbles was formed by the gas, and then striking this mass with a proof plane, which became charged oppositely to the generator. The hydrogen could not be made to part with its charge even by driving it through water, but it became neutral if allowed to stand for four or five hours.

When hydrogen gas, which had lost its charge by standing a sufficient length of time, was allowed to bubble through water, no electrification was produced, and the author attributed this to the surface of contact between the gas and the liquid being insufficient to produce a sensible electrification.

DISCUSSION.

In the discussion which followed,

Prof. RÜCKER inquired if the author had observed whether a change took place in the sign of the electrification if the zinc were introduced in the first place into a solution of zinc chloride, and hydrochloric acid subsequently added.

Dr. BURTON suggested that the hydrogen should be shaken up with the liquid in a bottle, which might possibly produce sufficiently intimate contact to give an appreciable result.

Mr. ENRIGHT, in reply to Prof. Rücker's question, stated that he had tried the effect of beginning with zinc chloride in solution, and that the deflection could be reversed again and again by adding acid whenever the amount of the chloride became so great as to produce a deflection opposite to that with the pure acid.

THE SIEMENS AND HALSKE TRANSFORMER.

At the recent Berlin Exhibition Messrs. Siemens and Halske had an interesting historical collection of the various types of dynamos built by the firm during the last twenty years. Among others they showed a flat ring armature machine of 1869, their first alternator of 1875, and the first compound, built in January; this latter was at work in Berlin from 1883 till 1887. They also showed their newest inside magnet machine, which was referred to in *The Electrician* of November 1st, p. 647. In the annexed figure is shown the exterior of the Siemens' transformer, of which two were exhibited, one 5 and one 10-unit. The construction is not very lucidly described; but we gather that an equivalent of the Kent shield is used, consisting of a thin tertiary coil between the primary and secondary, one end of the tertiary being earthed and the other open. The *Elektrotechnische Zeitschrift*, from which we extract these details, merely remarks concerning the terminal board of the transformer that it is made of insulating and fire-proof material, carries four lead fuses, and the terminals of the *primary and secondary* coils.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 9, 1889.

The Postmaster-General and the Western Union Company.—It will be remembered that a few weeks ago Postmaster-General Wanamaker fixed a tariff for the ensuing year for Government telegraph messages, at the extremely low rate of one mill (or one-twentieth of a penny) per word. This rate was so evidently below the actual cost of the service, that not only did the Western Union protest strongly, but its complaints were echoed by a large number of newspapers, which, as a general thing, are very much averse to saying anything in support of monopolistic interests. For a short time Mr. Wanamaker stood his ground, and attempted to justify his action, but he has now been convinced of his error and has revised his scale of payments. He now fixes the rates at an average of 10 cents a message of not more than 10 words, exclusive of date, place of dispatch, address and signature, for all distances not exceeding 400 miles. For night messages, the corresponding rate is 15 cents for 20 words. The whole scale for longer messages and greater distances is adjusted to this basis. In writing to Dr. Green on the subject, Mr. Wanamaker says that he does not admit that the privileges accorded to telegraph companies by Congress are of no value, but that, on the contrary, he is convinced that the Government is entitled to very special consideration in rates, &c. With the view, therefore, of determining what Government rates shall be for the future, he proposes the appointment of a Commission of five suitable persons, who shall inquire and report as to the actual cost and proper value of telegraphic service. This proposal for a Commission is innocent enough on the surface, but it seems to have escaped public notice that it might lead to important results. It is, in fact, one of the provisions of the telegraph law of 1866 that, whenever a Commission appointed in this manner appraises the value of any telegraphic plant, it can be purchased by the Government upon the necessary authority and appropriation from Congress. There has been not a little expectation that Mr. Wanamaker might recommend to the coming Congress the establishment of a Government telegraph system in connection with the Post Office. It will be seen at once that, if he shall succeed in obtaining his Commission, he might unostentatiously be placed in possession of specific information upon which he could base a definite scheme. At present, of course, we are pretty much in the dark as to what Mr. Wanamaker's intentions in the matter are, and we shall not know until President Harrison makes his address to Congress.

Storage Battery Patent Litigation.—There has been a very general feeling of regret among electricians and on the part of the public in this city at the stoppage of the Julien storage cars on Fourth Avenue, where, by this time, from 15 to 20 cars had actually been got ready and put in operation. These cars have stopped under the decision of Judge Lacombe, in the United States Circuit Court, which prevents the Julien Company from making their plates in various ways the right to which is ascribed to the Electrical Accumulator Company, and which leaves open to them the method whereby a perfectly dry powder is compacted upon the grid by hydraulic pressure and no fluid is added until the plate goes into use in the battery. The Julien people, it would seem, have been trying to accommodate the Court so as to make their plates in such a manner as to satisfy the judge that there was no infringement, and now that they have ascertained just what the judge deems right they will go ahead as briskly as at first, and will produce as many of the dry-powder plates as may be required. The company make the statement that these absolutely dry plates are far better than they had anticipated, and that they will answer their purpose better than any that they have employed heretofore. This dry-powder method is claimed as covered by one of the early patents of Mr. B. Brush, but this does not have any material bearing upon the case, it would appear, as it is rumoured that an alliance between the Brush and Julien storage battery interests exists. In fact, it is asserted that the Courts will probably sustain one or more of Mr. Brush's patents in which is granted broadly the mechanical application of the active material in any form to a separate plate, whether that active material be a paint, paste, plaster, powder, or anything else beginning with a "p." Should that be the case, Mr. Brush, or his representatives, would control the situation; but for the present the Electrical Accumulator Company are very well satisfied with the aspect of things, and propose to enforce as thoroughly as possible their rights with regard to manufacturing plates in which the active material takes the form of a paint, paste, or cement.

Flake Mica as an Insulator for Electrical Conduits.—The frenzied discussion in the public prints as to the safety or danger of overhead wires has naturally diminished somewhat, it being impossible that the pitch could be maintained. Of course, all this discussion has given a tremendous impetus to the production and exploitation of high-insulation wires, and it has also greatly stimulated ingenuity in regard to subways and conduits. One interesting new scheme which has been put forward in Boston is to run the wires through ducts which have been filled up with flaked mica. In such ducts the wires can be easily pulled through, as the material is yielding. The pipes would be made of indurated fibre, and the insulation of the wires would consist of only one dry-cotton braiding. It is claimed that when the wire is in the conduit and thoroughly embedded in the flaked mica, no moisture can possibly attack the insulation, and that as long as the cotton can be kept dry the insulation will, of course, be maintained perfect. Various objections to this scheme suggest themselves, one of which is the difficulty of obtaining pure mica in sufficiently large quantities; but there seems a likelihood that the scheme will be tried, and then we shall know more about it.

The Pittsburgh Reduction Company.—A few weeks ago reference was made in this letter to the method of the Pittsburgh Reduction Company for the production of aluminum. This concern has now made a most surprising cut in the prices of aluminum in the form of ingots. It announces that it will sell 1,000lb. lots at $2 per lb., 500lb. lots at $2.25 per lb., 100lb. lots at $2.50 per lb., 50lb. lots at $3 per lb., and small lots at $4 per lb. Up to the present time the lowest quotations on aluminum have reached from $4 to $6 per lb., but, as will be seen, the price is now quoted as low as $2. Such a reduction as this will undoubtedly do much to stimulate the use of the metal, with corresponding benefit to the Company. It may be that the Company has resorted to this policy as a means of advertising itself, for undoubtedly the announcement will be universally noted, but, on the other hand, there is no good reason to doubt its desire and ability to fill as many large orders as it can possibly get at these very low prices.

Electricity and Mining.—Speaking of aluminum reminds me that Mr. George Westinghouse, jun., who has so many irons in the fire, and who certainly has most wonderful success in keeping them all red hot, has just added to the list of his enterprises. This new departure is the purchase of some valuable copper mines in Arizona, and Mr. Westinghouse has formed a company to operate the property. The production will be used at Pittsburgh in the operations of the Westinghouse Electric Company, which uses several millions of pounds of copper every year, and which by having its own mines stands to save a great deal of money. The mines will give employment to about 300 men, and the work will begin almost immediately. It is somewhat a matter of surprise that other companies have not already undertaken similar operations, so as to save money for themselves in this way. In fact the connection between electricity and mining promises to become very much closer than it has been hitherto. It is no secret that many of the companies now engaged in the production of electric motors and electric power apparatus in general are turning their energies in the direction of mining work, and while not neglecting the stationary motor field and the street-railway business, are reaching out for these new and inviting fields in the mining industries of the country. It may even be said that the interest in the subject is even greater among the mining men than it is among the electricians, for the mining men perceive how, by the utilisation of distant water-power, they will be able to derive rich returns from mines where the cost of production has been so enormous as to offset the value of even the highest grade ore. During

Digitized by Google

the present week I heard of several very interesting installations actually started or about to be equipped, and there will soon be some important news in connection with this department.

The New Western Union Cables.—Just at the present moment the cable-laying steamer "Faraday" is off our shores, and is preparing to lay the first shore end of the new Western Union cables between Coney Island and Canso, N.S. Two cables are to be laid, and it is proposed to render the service between New York and Great Britain free of the interruption due to the winter storms which have so often broken down the land lines on this side. It is interesting to note that, although there has been not a little talk of late in regard to the desirability of pushing submarine cable-laying enterprises, the Western Union Company still goes abroad for its cables and for the people to lay them.

CORRESPONDENCE.

THE CITY AND GUILDS TECHNICAL EDUCATION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: While thoroughly agreeing with the opinions expressed in the able leader in your last week's issue on "The City and Guilds Technical Education," there are two points I should like to refer to in order to avoid misconception. It is stated in reference to the work of the Central Institution—"The value of work of this kind is not to be measured merely by the numbers who are trained in this manner; and, indeed, it would not be advisable to turn out men of this kind in any very large numbers, for the simple reason that it would be impossible to find places for them all." The reason I think, however, why it would be impossible to find places for a large number of students if turned out by the Central Institution would not arise from want of openings, but because it would be impossible to give large numbers the individual attention which the present students receive in the workshops, laboratories, and in drawing offices; and, therefore, it would be impossible to turn out large numbers with the thorough training that the present students now obtain.

In speaking of the lowness of the fees at the Central Institution it is stated in your leader:—"We, on the other hand, are inclined to agree with the majority of those who send their sons there, and who are almost unanimous in their wonder at the extreme lowness of the fees compared with those which they would have to pay for from three to five years if their sons were apprenticed to an engineering firm; and students after leaving the Institution, except in cases of exceptional ability, usually find that they have to pay more for their final year, spent in an engineer's workshop, than for their three years at this Institution." From this it might fairly be concluded that it was the usual thing for students who had passed through the Central Institution to pay a premium when entering a manufactory, but, as far as I am aware, of all the students who, on completing the course at the Central Institution, have gained the diploma and "Associateship of the Institute," only one has ever paid a premium on entering a manufactory, while many of them have commenced receiving a small salary of a couple of pounds a week directly they left this college.—Yours, &c., W. E. AYRTON.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your note in last week's issue practically demolishes the elaborate structure raised by "Observer" on wrong bases, and therefore it is not necessary to reply to the arguments and deductions which he has "excogitated from his inner consciousness," as the German philosopher did the camel. "Preponderance" forsooth, when our protest is only raised against annihilation! It does not require a large black board and a quantity of chalk to demonstrate the vast difference between preponderance and *extinction*, and I am confident that the modest desires of the telegraph fraternity will be quite satisfied with two or three representatives on the Council. If, in addition, the mathematicians will remember that we are an indispensable factor in the progress of the world, and that our profession has altered the relations of all civilised nations, and is by far the most important application of electrical science, the need of a new Society will pass away.

If the present Institution were fully representative of all branches of the science, there would be no room for another Society. But what are we to do with such Councils as we have had for the last three years, and how long are we to remain members of a Society which has ceased to interest or instruct us? The blame of the threatened schism must rest with the Councils which have seen one after another of the most prominent telegraph members sending in their resignations, and which have confined themselves to writing conventional letters of regret without considering whether or not their own policy was to blame. Their very confession of the extraordinary oversight of Land and Submarine Telegraphy, at the recent dinner, is evidence that our profession had passed completely out of their thoughts, and their complaint that Papers on Telegraph matters have almost ceased is a further proof that the Institution has ceased to claim the attention or satisfy the needs of Telegraph men. Strongly as I would deprecate the formation of a new Society—at least until we see whether our just claims cannot be met—it is only right to add that the new venture has been taken up with alacrity in high circles, and several excellent and novel features suggested, which would make it something much more than a mere scientific Society. I would strongly urge, however, that these new features should be kept for the strengthening and broadening of the old Society—that is, if we can make the Council representative of the whole science of Electricity.

It must be remembered that the complaints against the Council are not confined to Telegraphy, for other branches are at least equally ignored. It is true there are no Postal Telegraph successors to Messrs. Preece and Graves, but it is equally true that there never was a Telephone representative on the Council, nor is there any Railway Telegraph Engineer to succeed Mr. Spagnoletti when he shall have retired to a well-earned repose. Where are the "cable" men to fill the places of Willoughby Smith, Weaver, Andrews, and Ansell? "Instead of which" there are no less than *thirteen Professors*, three or four Military, and a number of Electric Light men. "This will never do," as Jeffrey said of Keats' "Endymion." Mathematics and arc lamps form only a portion of the resources of civilisation, and if the Council were composed, say, of two representatives of each branch—Postal Telegraphy, Ocean Telegraphy, Railway Telegraphy, Military Telegraphy, Electric Light, Telephony, and manufacturers, we should probably have a Council which would neglect no interests and blunder into fewer apologies through lack of catholicity.—Yours, &c.,

TELEGRAPHY.

ELECTRICAL INSPECTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Now that the question of Board of Trade regulations and of the Model Provisional Order has been settled, so that *bona fide* companies can, on satisfying the powers that be of their financial capabilities, carry out their schemes, it is most important that everyone should have a clear and correct idea of the protection afforded to undertakers as well as to the public, who, as a body, cannot protect themselves.

On looking through your valuable paper there will be found many utterances of opinion on subjects affecting the legal phase of central station lighting. On page 428 of August 10th of last year, in an editorial article dealing with the electrical inspector question, you say that "either the undertakers or the consumers are at liberty to require the inspector to test the accuracy of any current or energy meter." Now this is not so as regards a current meter, there being no regulation in the Acts or Orders that requires or takes notice of the current rate, with the exception of the clause mentioning the "maximum supply demanded by the consumers." The points raised are those only of pressure and of quantity of electricity. Probably the word "current" ought to read "quantity."

Digitized by Google

I might also point out that nothing is said in the Orders about the testing of quantity meters until complained of by either party to the transaction of selling and buying electrical energy beyond the word "correct" before the word meter. There is no compulsory testing on the part of the electrical inspector before sealing, provided he is convinced the instrument is a "correct meter."

You then quoted the words "competent and impartial," as applied in the Model Order to the individual above mentioned: it may not be amiss to mention that only one adjective is *now* applied, and certainly with greater correctness. You remarked in this connection that it would be necessary to appoint an electrical inspector-in-chief. This post in reality, though perhaps not in name, is now held by the Electrical Adviser to the Board of Trade, a gentleman who certainly comes up to your standard, being one who is "not merely qualified by technical knowledge and ability, but also by actual experience of electrical engineering on a commercial scale."—Yours, &c., CHARLES H. YEAMAN.

Liverpool, November 14th.

A LONG-LIVED INCANDESCENT LAMP.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It may interest you to know that an incandescent lamp (Woodhouse and Rawson), which was put up on September 2nd, 1888, and which has been burning continuously ever since, has now burnt out, after the phenomenal life of 10,608 hours.

As this was a 98-volt lamp, and was on the charging leads of a 50-cell battery, you will see that during a considerable part of its life it was burning a good deal above its nominal candle-power.—Yours, &c., ORLO. V. THOMAS,

Taunton, November 20th, 1889. Electrician-in-Charge.

LEGAL INTELLIGENCE.

COURT OF APPEAL.

The Queen v. Redman.

This was an appeal heard before the Master of the Rolls, Lord Justice Lindley, and Lord Justice Lopes, on Thursday last week, from the decision of a Divisional Court, reported in *The Electrician* of November 1st. The London Electric Supply Company had erected at Deptford very large buildings, the eastern wall of which adjoined the premises of the General Steam Navigation Company. The buildings were completed in March, 1888, and in November, 1888, the General Steam Navigation Company discovered by digging that the wall had not proper footing as required by section 12 of the Metropolitan Building Act, 1855. Mr. Redman, the district surveyor for North-East Deptford, having refused to put in force the provisions of the Act, and to compel the London Electric Supply Company to comply with it, the General Steam Navigation Company obtained a mandamus to Mr. Redman to compel him to enforce the Act. From this Mr. Redman appealed.

Mr. FINLAY, Q.C., with Mr. BREMNER, for the appellant, contended that it was not a case for a mandamus. He read the affidavits of a large number of surveyors to the effect that the building was perfectly safe and substantial. The district surveyor had a discretion under the Act, and if he considered, as he did, that the building was perfectly safe without the footing required by the Act he need not insist upon it. It was impossible now to fulfil the provisions of the Act without pulling down the whole building and recommencing it. No magistrate would direct that to be done in the case of a building which was perfectly safe.

The ATTORNEY-GENERAL and Mr. C. A CRIPPS, for the General Steam Navigation Company, said that the case was one of great importance. The General Steam Navigation Company employed some 400 workmen on these premises, whose safety was endangered by this wall. The statute left no discretion in the matter, but required certain footings to every wall. It had been in force many years, and the surveyor had no discretion to vary the minimum given by the statute for safety. The question of safety could not be determined in these proceedings. When the magistrates came to consider the question of penalties, that question might arise, but it could not be raised now.

The MASTER of the ROLLS said that the Court would not give judgment for a fortnight, and meanwhile the parties would do well to come to some arrangement.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

October 25, 1889.

16,839. J. PERRY. London. An electric supply meter.

16,847. H. J. ALLISON. London. Improved system of electric generation and apparatus (J. I. Conklin and W. H. Rushforth, United States).

16,879. C. P. ELIESON. London. Improvements in and connected with electricity meters.

16,887. F. H. W. HIGGINS. London. Means for ascertaining the state of the vacuum in incandescent electric lamps.

16,890. E. FRANKLAND, A. H. HOUGH, and D. G. FITZGERALD. London. Improvements in elements for secondary batteries.

October 26, 1889.

16,917. J. FARQUHARSON and F. V. ANDERSEN. London. Improved winding of armatures of dynamos.

16,947. A. DE MÉRITENS. London. Improvements in treating and rectifying or ageing alcohol or alcoholic liquors or the like by electricity.

October 28, 1889.

16,978. J. M. M. MUNRO. Glasgow. Improved arrangement of conductors for electric series traction.

17,004. H. I. HARRIS. London. Improvements in electric terminals and switches.

October 29, 1889.

17,045. F. MORLEY. Cambridge. The insulation of electric wires or cables.

17,060. T. PACKER. Wolverhampton. Improvements in electrical furnaces and in their manipulation.

17,062. W. F. C. WARD. London. A miners' or safety lamp and battery.

17,075. P. HADEN. London. Applying electric current for heating rivets (H. H. Bales, East Indies).

17,115. F. X. BACHMANN. London. Improvements in electro-magnetic telegraph apparatus. (Dated October 30.)

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

17,118. L. PAGET and C. J. KINTNER. London. Improvements in and relating to electrical transformers or converters.

17,124. W. P. THOMPSON. Liverpool. Improvements in interrupting devices for electric circuits applicable for protecting electrical apparatus connected in such circuits (The Westinghouse Electric Company, United States).

17,138. T. C. DE BOYÈRES, Sen. London. Electric or electro-magnetic elements or rings, applicable to collars, muzzles, and other articles for use with animals for the purpose of preventing rabies in such animals.

17,142. L. BOLLMANN. London. Improvements in electro-magnetic induction apparatus for transformers, generators, or motors.

October 30, 1889.

17,221. H. L. TODD, W. F. MELBOURNE, J. THOMPSON, and R. E. M. MOSTYN. London. Improvements in electric telephonic apparatus.

October 31, 1889.

17,252. F. M. A. LAURENT-CÉLY and I. A. TIMMIS. London. Improvements in electric secondary cells.

17,260. W. H. OAKLEY. London. Improvements in holders for incandescent electric lamps.

17,274. G. S. GRIMSTON. London. An electric switch (partly communicated by Frank Jacob, at present on the high seas).

17,276. G. DONOVAN and W. DONOVAN. London. An improved socket and adapter for electrical purposes.

COMPANIES' MEETINGS.

The Australasian Electric Light, Power, and Storage Company (Limited).

We have been supplied with the following report of proceedings at an extraordinary general meeting, held at the offices of the Company, on Tuesday, the 12th inst., under the presidency of Mr. B. H. Van Tromp:—

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, it will be within your recollection that when we met in July last you passed a resolution approving an agreement which we had then entered into with the Brush Company. I then told you I thought it highly probable that certain arrangements would have to be made which would render necessary an alteration in the terms of that agreement, and I fully prepared the shareholders for the possibility of our calling another meeting to make a statement as to the new arrangements so entered into. I may mention also that at that moment the Brush Company were in a condition of transition, acquiring not only powers to increase their capital and powers to extend their operations by amalgamation with a manufacturing company, but to actually change themselves into a new company, and, therefore, we were advised by our solicitor, Mr. Ince, that for that reason alone, if for no other, it would be advisable to make a change in the arrangement. I also mentioned to you that, in consequence of the distance that separated us from our field of operations in Australia, we were not quite certain as to the precise condition of some of our patents. There were other matters, too, in abeyance there, upon which it was necessary we should be more fully informed, and now, under the advice of our solicitor, the Board has decided upon the new modification. By the present arrangement we do not propose to hand over to the Brush Company the whole of the assets of this undertaking, but we agree to sell, and indeed have sold, subject to your approval, the patent rights and goodwill of the business in India and the Cape, Australia, and Australasia generally, and also the shares which this Company holds in the Melbourne Company. We retain the whole of the other assets, comprising the plant in England, India, and Australia, book debts and various matters, including the balance of the call in course of payment. Under this arrangement, therefore, the Brush Company, under the name of the Brush Electrical Engineering Company, give us for the patent rights and the other assets I have mentioned, £30,000 in their shares. These shares will be divided *pari passu* among the shareholders of this Company. I may mention that the shares of the Brush Company are at a premium of 5s. to 10s. per share, so you will, I trust, be placed almost immediately in possession of assets which can be immediately realised and sold, if you desire to sell . . . It is a condition of the agreement that we shall within a few months liquidate this Company. We have made an arrangement with our purchasers that they themselves will provide the expenses of the liquidation, including the stamp duties on the transfers, &c., so that there will be no reduction on that account from the £30,000 in shares which you are to have. In addition to that, we shall do the best we can when we go into liquidation, and the proceeds of the other assets we shall divide among the shareholders *pro rata* according to their holdings, so that we hope in addition to the shares which we shall hand over to you, to return you something in cash. . . . Mr. Ince informs us that we are now in a position to transfer our patents without encumbrance and without any difficulty whatever to the new company. I now beg to formally propose the following resolution:—

"*It is hereby resolved to adopt, ratify, and confirm the agreement, dated the 23rd day of October, 1889, and made between the Australasian Electric Light, Power and Storage Company (Limited) of the one part, and the Brush Electrical Engineering Company (Limited) of the other part; and the Directors are hereby authorised and requested to do all things that may be necessary for the purpose of giving effect to the said agreement, and carrying out the provisions thereof, either with or without modification.*"

Mr. TURNER seconded the motion.

The CHAIRMAN, in reply to questions from shareholders, stated the shares would be issued as fully paid, and would be divided in the proportion of two-fifths Preference and three-fifths ordinary, the former bearing a preferential dividend of 6 per cent. There would be no further liability of any kind or description attaching thereto, and the Board hoped shortly to be able to call a meeting to formally wind up. As to the unpaid calls, those who had not paid the final call would get nothing, so that it would be to the interest of all to pay up any calls that might be in arrears. There was a possibility of a slight reduction from the £30,000, owing to the possible extinction of one of the patents in Australia. He did not think this contingency at all likely to occur, but had the fullest belief that the shareholders would receive the whole of the £30,000.

The resolution was then put and carried unanimously.

A cordial vote of thanks to the Chairman and Directors for the very satisfactory way in which the negotiations had been conducted, proposed by A SHAREHOLDER and seconded by the Rev. W. J. STOBART, brought the proceedings to a termination.

The CHAIRMAN intimated to the meeting that the proposals of the Directors had met with opposition from only one shareholder with five shares.

CITY NOTES, &c.

BATAVA (LIMITED).—This Company was recently registered with a capital of £100,000 in £1 shares, and amongst the businesses which it is formed to undertake is that of tinsmiths, waterworks proprietors, electricians, electrical engineers, suppliers of electricity and of the electric light, and any other business incidental to or arising out of, or which can be conveniently carried on in connection with such businesses. There shall not be less than three nor more than eight directors.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 15th amounted to £5,204.

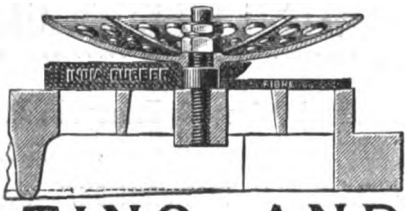
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 15th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,714.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended November 15th amounted to £2,841, as compared with £2,319 in the corresponding period last year, an increase of £522.

PERSONAL.—We understand that Mr. Gisbert Kapp has taken offices at 31, Parliament-street.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept'. 1385.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 602.—Vol. XXIV. FRIDAY, NOVEMBER 29, 1889. Price Fourpence.

NOTES.

We learn that Sir James Anderson, Sir Albert Cappell, and Sir Henry C. Mance have been invited to allow themselves to be nominated for the Council of the Institution of Electrical Engineers for the ensuing Session. These gentlemen being prominent representatives of cable and telegraph interests, their election on the Council would afford much satisfaction to a large section of the members, and go far to allay the irritation which has lately found expression in our columns.

The question has occasionally been asked, how it is that there is no one on the Council of the Institution of Electrical Engineers who can be said to represent the telephonic interests? It is not a new complaint; but the non-representation of telephone men is even more striking than the small representation of cable men to which attention has lately been called. We believe that the true reason for this strange state of things is as follows; at least we have it on the authority of one who ought to know:—During the time that the late United Telephone Company was waging legal war on all competitors, permission was refused to any of the persons in the employ of the United Telephone Company to read scientific Papers at the Institution on telephonic matters; and more than this, the *employés* of the United Telephone Company were actually *forbidden* to attend the meetings of the Society. American telephonists who contrast this with the active part taken by telephone men on their side in the business of the American Institute of Electrical Engineers, and other electrical bodies, will now perhaps comprehend why progress on our side has been so slow.

The reply of Mr. Lee Babty to the report of the Special Committee of the Electrical Trades Section may be deemed, except on the one important question of insurance, as fairly satisfactory. If the Executive Committee of the Exhibition persist in their refusal to undertake the insurance of exhibits, it is to be hoped that they will, at least, see their way to minimise the insurance premiums by erecting weather and fireproof buildings, and by organising an efficient fire brigade.

We think it is to be regretted that the Exhibition authorities were unable to do more than offer to supply the power in the event of electrical tests being undertaken. The cost of such tests would, no doubt, be considerable, but their scientific and commercial value would be great. Exhaustive tests by a competent jury of the alternators and transformers of the leading English and American makers would, we think, be a feature likely to contribute largely to the general success of the Exhibition.

On another page we give Mr. Brooks' views as to the Brooks' System. For telegraphic and telephonic purposes that system has, we believe, given very good results, and it is to such work that most of Mr. Brooks' observations specially refer. Our readers will note that little or nothing is said by the originator of the system as to any modifications that may be necessary to adapt that system to the very different conditions obtaining when the object is to put down, to protect, to repair, or to replace the heavy conductors that are demanded in connection with electrical distribution as understood by the "heavy electrical engineer." The subject is an exceedingly important one, especially at the present time, when very large sums of money are being expended in underground work. Even from the point of view of the proverbial "man in the street," there seems to be room for considerable improvement in some of the work and methods that may be inspected daily in London. We trust that we are not mistaken, but we are forced to one of two conclusions by our observations—either that before long considerable repairs will be required, or that the laying of underground conductors in a permanently satisfactory way is a much easier matter than has generally been believed.

Whether Mr. Brooks' system, when used for large currents and high electromotive forces, will be quite satisfactory we shall be very glad to learn, not from an *ex parte* statement, but from some account of its prolonged use on a practical scale. We imagine, however, that before it has any chance of being tried in this country a large number of special devices and arrangements must be prepared to fit it for the conditions that exist in connection with town lighting, not the least of which will be to provide suitable means for frequent tapping of the mains—though we do not, for our part, anticipate any very serious difficulties in this matter.

Electrical tramways have hitherto been worked according to one or other of the following plans—aerial conductors, rail conductors, conductors in conduits with open slot, and accu-

Digitized by Google

mulators. Each of these plans has advantages—and disadvantages. There have at various times been indistinct rumours of systems that professed to have all the advantages and none of the disadvantages of conduits. Such a system is undoubtedly attainable, if high first cost is not included among the disadvantages. We give this week a short description of a method which is a closed conduit method, and we draw the attention of electrical tramway men to it as at any rate pointing in a direction that appears to invite careful examination.

THE National Telephone Company is threatened with opposition in several of the principal provincial towns by a project for establishing what is called Co-operative Telephony, all the users binding themselves together to pay the cost, and no more than the cost, of erecting and working wires of their own. We cannot be sure of the *bona fides* of the proposal, for we find the same financial organs which not long ago were encouraging the telephone companies in their amalgamation now backing up the rival scheme as being directed against a gigantic and mischievous monopoly whose patents are happily expiring. Of one thing, however, we are pretty sure: the new competitors will have to gain the consent of the POSTMASTER-GENERAL; and, patents or no patents, will have to pay royalty to the Post Office.

IN a long letter to the *Scottish Leader* of the 20th, Mr. A. B. BROWN, of Rosebank Electric Works, discusses, for the benefit of the Edinburgh Town Council, the various existing systems of electrical distribution. The alternate-current high-tension system is dismissed on account of its danger, anent which Mr. BROWN remarks: "I do not think it rash to forecast the probability that in the end, and that is not far distant, this system will be prohibited by law." For our own part, remembering, as we do, that there have been alarmist proposals to limit train-speeds, boiler-pressures, and what not, we do not think it rash to predict that such a prohibitory law will never be placed upon the Statute book. If experience shows that the dangers of a high-tension alternate-current system of distribution are greater than its advantages, its extinction will be automatic, and legal prohibition will be quite unnecessary. The next system which is weighed by Mr. BROWN and found wanting—this time owing to its costliness—is that of battery sub-stations. This process of elimination leaves us "the 100-volts, harmless, simple, continuous system," which, with the dynamos worked by "a highly explosive, but non-illuminating gas," to be supplied by the Gas Commissioners to the various centres, in separate pipes, is the circumlocutory method of distribution which, in Mr. BROWN'S opinion, ought to find the most favour with the Edinburgh authorities.

WE hear that Messrs. W. T. GOOLDEN AND CO. are now constructing a modified type of continuous-current dynamo, the special feature of which is that the armature and field-magnet poles are so disposed that, in the event of any coil burning out, it can be at once replaced *in situ* by any intelligent workman of ordinary skill.

NOTHING daunted by the untimely fate of the Electric Subway Railway Bill in the House of Commons last Session, it is proposed next year to bring forward a somewhat similar scheme. Last year the idea was to run a spacious subway a few feet below the roadway, the line starting in the neighbourhood of Piccadilly and terminating in the heart of the City. The present proposal is to pierce the London clay at a depth of 40 or 50ft. with two steel tubes, after the fashion of the City and Southwark Subway, and to run a line from Queen's-road, Bayswater, to the King William-street terminus of the City and Southwark Subway. The engineers are Sir JOHN FOWLER, Mr. BENJAMIN BAKER, and Mr. GREATHEAD; and we think it will be pretty generally agreed that the carrying out of the scheme could not be in better hands.

DO any of our studious readers ever consult that most interesting volume, the Catalogue of the Ronalds' Library? They will find many curious entries, some of great value, others of a singularly trivial nature. "On the Electricity of a Parrot's Wing" is the title of one of the items. Another title entered in the catalogue is "The Desideratum, or Electricity made Plain and Useful, by a Lover of Mankind and of Common Sense." The author of this curious work is no other than the Reverend JOHN WESLEY. The date of the book was 1759, but it appears to have been reprinted as lately as 1871.

OUR esteemed contemporary the *English Mechanic*, which does so much to bring practical science within the comprehension of the non-technical, and which is virtually the organ of communication between scientific amateurs of all ranks, is just now enlightening its readers respecting the "new" theory of sound originated by Dr. A. WILFORD HALL. The new theory, which is to demolish the wave theory, is that sound consists of corpuscles of different sizes that fly through space. How they fly through solid wires remains to be told in a future number, the issue of which we await with interest. In particular we want to learn how telephonic sounds are transmitted. Are the corpuscles that come out of the speaker's mouth transmitted "in a fluid state" through the electric wires, or do they merely set up electric disturbances which breed at the distant end a new crop of corpuscles? We crave for a clear and full explanation.

THE rumour that Mr. J. E. H. GORDON had ceased to be engineer to the Metropolitan Electric Supply Company is, we hear, without foundation. When the Metropolitan Company was formed Mr. GORDON was appointed head of the engineering staff as a salaried officer, and undertook both the work of designing new and working completed stations. Owing, however, to the rapid development of the Company's operations it was recently decided to make a division of duties, the designing and carrying out of new work being left in the hands of Mr. GORDON, while the general management of the engineering department was given to Mr. BAILEY, who has for some time past afforded valuable assistance to Mr. GORDON, who still remains engineer to the Company under an arrangement usual in such cases.

Digitized by Google

Morecambe.—Application has been made by Messrs. Andrews and Preece, of Bradford, for a Provisional Order.

Salonica.—The *Revue de l'Orient* of Budapest states that several offers have been made to light Salonica by electricity.

Darlington.—At a special meeting of the Town Council last week, it was unanimously resolved that application should be made for an electric lighting Provisional Order.

Personal.—On account of Mr. Fahrig's indisposition, the demonstration and lecture on "Ozone," at the Ozone Works, is postponed. Invitations will be re-issued at soon as convenient.

The Lighting of the City.—Notices of application for electric lighting powers within the City were published this week by the Brush Company and the London Electric Supply Corporation.

St. Helens.—The Town Council has decided that steps shall be taken to apply for a Provisional Order to supply electricity in the districts within the area of the gas supply of the Corporation.

Royal Institution.—The Christmas lectures (adapted to a juvenile auditory) will this year be given by Prof. A. W. Rücker, F.R.S., on electricity. They will commence on Saturday, December 28th.

Electric Traction on the North Metropolitan Tramways.—The North Metropolitan Company have this week advertised their intention of applying for powers to work the whole of their system by electricity.

Newcastle.—The Town Clerk has been instructed to confer with the representatives of the electric lighting companies with a view of arriving at an agreement which will empower them to proceed with their work.

Chatham.—The Admiralty have decided that Chatham Dockyard shall be lighted by electricity, and have directed preparations to be made for the lighting of the ships and workshops with the new illuminant.

Electric Traction at Doncaster (Victoria).—An electric tramway, 2¼ miles in length, on the overhead Thomson-Houston system, has come into operation at Doncaster (Victoria). A pressure of 400 volts is employed.

Havana, Cuba.—The electric lighting plant of the Spanish-American Gas, Light, and Power Company, of this city, now comprises three 1,500-light Westinghouse alternating machines, and six 50-light Thomson-Houston arc machines.

Surbiton.—At a special meeting of the Improvement Commissioners last week, it was agreed that application should be made, in combination with the local authorities of Kingston, New Malden, and Hampton Wick, for a Provisional Order.

Proposed Electrical Exhibition at Frankfort.—The Electrotechnical Society of Frankfort has unanimously decided to hold an electrical exhibition in this town next year, and a committee of eighteen members has been formed to take the necessary steps.

Barnsley.—At the last meeting of the Town Council the draft Provisional Order presented by the Town Clerk, which had been thoroughly revised by competent parties, was ordered to be printed and placed in the hands of all the members of the Council.

A Correction.—In our note last week on the electric lighting of Alnwick Castle, the batteries were stated to be E.P.S. type. We are, however, informed by Messrs. Drake and Gorham that they are the same pattern which have been fitted by them in so many installations.

Mill Lighting.—Thorverton Mills, Devonshire, which have been fitted up with every improvement in the matter of turbines and rollers, have now been lit by electricity. This work has been carried out by the firm of Messrs. Christey, Son, and Norris, of Chelmsford.

The Electric Light at the British Museum.—Most of the galleries in the British Museum will, it is stated, be open to the public, commencing 1st January next, from 10.0 a.m. to 10.0 p.m. The electric lighting is now ready, new machinery having been put in and tested.

The Copper Market.—The price of copper is again rapidly rising, in consequence, it is said, of the abnormal purchases of the German and French Governments, who have decided to reconstruct their naval and military ordnance, replacing steel, to a large extent, by gun-metal.

Padiham.—At the last monthly meeting of the Local Board it was intimated that the two electric lighting companies who had given notice of applications for Provisional Orders had withdrawn the same, and the Board decided not to proceed with their application for the same powers.

Ealing.—The application of the Maxim-Weston Company for consent to their proposed Provisional Order was discussed at considerable length at the last meeting of the Local Board. It was finally decided to adjourn the meeting, with the view of obtaining advice from the Board of Trade.

Dundee.—At a meeting of the Electric Light Committee of the Town Council, Police Commission, and Gas Commission on Monday, it was agreed to take the opinion of Dr. Hopkinson, as to the expense and all other matters connected with the installation of a system of electric lighting in Dundee.

The Electric Lighting of the Houses of Parliament.—The contract for lighting the Houses of Parliament by electricity has been given to the Westminster Electric Supply Corporation, and active steps are being taken to carry it into effect. It is proposed to make a large extension of the existing installation.

The Chair of Engineering in Yorkshire College.—The Council of the College have elected Mr. John Goodman to succeed Prof. Barr in the chair of Civil and Mechanical Engineering. Mr. Goodman, who is 27 years of age, is at present chief assistant at the Broadway Testing Works and Chemical Laboratory, Westminster.

The Telephone in Kent.—The South of England Telephone Company are just finishing an extension of their system at Deal, Kent, and the wire to Whitstable will be opened in another fortnight. The Ashford Trunk Line will then be commenced, prior to opening up communication between Maidstone, Chatham, and East Kent.

Tynemouth.—At a meeting of the Town Council last week it was decided not to proceed further with the application for a Provisional Order. The action of the Council is based upon the withdrawal from action in the matter by the electric lighting companies who had previously intimated their intention to apply for powers.

Technical Education.—At a Conference of the National Association for the Promotion of Technical Education, held at the Manchester Town Hall last Tuesday, a report was read by Sir Henry Roscoe, showing that a large number of towns throughout the kingdom have already adopted, partly or wholly, the Technical Instruction Act of 1889.

The Lighthouse Illuminants Inquiry.—Sir William Thomson has been selected by the Board of Trade to take the place of Sir William Grove on the Committee appointed to inquire into the correctness of the allegations of shipowners and others against the conclusions of the Trinity House report on the South Foreland experiments with lighthouse illuminants.

The Central Station at Tivoli.—The plant of the central lighting station now in course of erection at Tivoli will comprise six 350 horse-power Girard turbines and three 50 horse-power Girard turbines; six 5,100 volt 45 ampere alternators and three 180 volt 150 ampere machines. The station is expected to be ready to supply current by August next.

Worcester.—At a meeting of the Watch Committee last week a report was received from the Gas Sub-committee with regard to the proposed application for a Provisional Order, proposing that the compulsory district should have a total area of about 103,000 square yards. The sub-committee estimated the capital expenditure at £15,000. The report was adopted.

Festivity.—A complimentary musical *soirée* and ball was given at the Manchester Athenæum on Tuesday evening to commemorate the marriage of Mr. Kenneth Maciver, Manager of the Manchester district of the National Telephone Company. Mr.

Digitized by Google

Maciver was presented during the course of the evening with a gold repeater, and Mrs. Maciver with a fine pearl and diamond ring.

Carlisle.—The Corporation have been advised by the Town Clerk that the powers granted to them in the electric lighting Order, obtained by them several years back, have not lapsed through non-usage, but are perpetual. Acting on this supposition, the Corporation do not intend to apply for a new Provisional Order, but propose to take steps to supply electricity under their old powers.

Civil and Mechanical Engineers' Society.—On the 13th instant Messrs. David Kirkaldy and Sons received the members of this Society at their testing and experimental works in Southwark-street. Tensile tests were carried out in the presence of the visitors, who were next shown the well-arranged museum, containing specimens of every kind of material, which had been submitted to every kind of stress.

Institution of Electrical Engineers Students' Meeting.—At the students' meeting on Friday last a discussion took place on "Cotton, Jute, and other Fibrous Substances as Insulators," in which Messrs. Barton, Childs, Muir, Müller, Poynton, Tonge, and Walker took part. This was followed by a description by Mr. Childs of the pumping and hauling plant recently put in at St. John's Colliery, Normanton.

Leicester.—At a meeting of the Town Council on Tuesday a motion for the appointment of a Special Committee to report as to the best means of improving telephonic communication in the town was carried by a large majority. Great dissatisfaction was expressed at the restrictions which the Post Office seek to impose upon the use of the telephone, and it was proposed to ask the National Telephone Company to start an exchange.

Proposed Memorial to Dr. Joule at Manchester.—The Mayor of Manchester, in reply to a deputation of the Manchester Literary and Philosophical Society, who presented a requisition asking that he would hold a public meeting to consider the raising of a permanent memorial to the late Dr. Joule, said that he was entirely in accord with the purpose of perpetuating the great name of Dr. Joule. He would further the object in any way he possibly could.

A Smart Telephone Performance.—The *Cardiff Evening Express* mentions the following as an instance of smart work by the Western Counties and South Wales Telephone Company:—"It was three minutes after the game between the first teams of Cardiff and Gloucester had finished that the result was handed in at the telephone office, Working-street. In ten seconds the result was sent through the Gloucester office, where a large number of persons had assembled."

An Electric Tramway in a Distillery.—An electric tramway has been in operation for some little time at the Dublin Whiskey Distillery. The line is circular, and is about one mile in circumference. An overhead wire is used and current is obtained from the electric light dynamos. At present the principal use to which the railway is put is to carry the barrels of whiskey from the distillery to the bonded stores, but arrangements are being made by which the grain can be brought from place to place.

The Electric Light on the Suez Canal.—An official return shows that in the year 1888 the time occupied in passing through the Suez Canal by vessels not using the electric light was 37 hours 57 minutes on the average, whereas the average time occupied by vessels using the electric light, and thus being able to navigate the canal by night, was 22 hours and 32 minutes. The number of vessels passing through the canal by the aid of the electric light increased month by month with remarkable regularity; their number for the first three months was 295, whereas for the last three months of the year it was 516.

The Determination of Air-Temperatures at Great Heights.—For determination of the air-temperatures at great heights, the Berlin Society for Ballooning proposes to try a method of Herr Siegsfeld, who uses a thermometer, which, by closure of an electric circuit when certain temperatures are reached, gives a light-signal. Small balloons, each containing such a thermometer, will be sent up by night, and the light will affect photographically a so-called "photo-theodolite," while the height then attained will be indicated in a mechanical way. It is hoped that more exact formulæ for the decrease of temperature with height may thus be obtained.

Berlin.—According to the Berlin correspondent of *Industries*, the Berlin municipal authorities having formally sanctioned the contract to be entered into with the "Berliner Elektricitäts-werke," the latter have to at once increase their means of supply at the central station, now in course of construction, up to 28,000 horse-power, and to extend their mains to the limits defined in the contract of August, 1888. The Company is bound to supply currents on demand to every householder in the streets through which their cables run. The Monnier conduit is being extensively introduced for the conveyance of underground electric light wires.

The Telephone Company of Rio de Janeiro.—The concession of the present Company was to expire on the 31st ult., but there appeared to be little likelihood, according to advices of the 28th ult., that it would be able to dispose of its plant. From the fact that on October 24th seven new proposals were opened at the Department of Agriculture for the construction of telephone lines in the city, it looks as though the Government had decided to ignore altogether the wires of the old Company. Just as the mail left there was a rumour that the Company had succeeded in privately disposing of their lines, posts, and other material for a sum of 400,000 milreis (£45,000).

St. James's (Westminster) Vestry.—At the last fortnightly meeting of this Vestry, the Lighting Committee reported that the London Electric Supply Corporation had secured, to the satisfaction of the Board of Trade, the sum of £13,000, the amount stipulated in their order, and that they were in a position to discharge the duties and obligations imposed upon them. They recommended that no objection be offered to the laying of mains by the Corporation, but that they should be requested to proceed as rapidly as possible with the work, in order that the surface of the streets affected thereby might be reinstated before the opening of Parliament. The report and recommendation were carried unanimously.

Railway Signal Devices.—We described in our issue of September 13th some ingenious electrical railway signal devices due to Mr. Henry J. Peddie, of Edinburgh. By means of one the brake was automatically applied to a train accidentally "running the signal," and by means of the other the signalman was able to trace the passage of the train along his particular section. Mr. Peddie's latest device is one which causes alarm bells to be rung and danger lamps to be lighted, both in the signal cabin and on the engine, whenever a danger signal is passed. Devices of this description are by no means new, but they have hitherto failed to come into general use, their expense, doubtless, proving a formidable deterrent.

A Peculiar Earth.—A peculiar earth, very similar to that which recently occurred in Boston and which was alluded to in *The Electrician* of August 9th, was discovered some few weeks ago on the Boulevard des Capucines. As at Boston, it was noticed that horses manifested considerable uneasiness on passing over a particular portion of the roadway. The electric light company was communicated with, and on the roadway being dug up it was found that the lead cover of the branch conductor to the street lamp was in contact with one of the bare main conductors, and as the neutral wire was faulty in several places a circuit was completed through earth between the lead cover and the neutral wire. The iron hoofs of the horses made excellent contact with the damp wood of the roadway, and the unfortunate animals consequently became a shunt on this leakage circuit and received smart shocks.

The Institution of Civil Engineers.—The following are some of the subjects on which the Council of the Institution of Civil Engineers invites original communications:—The Utilisation of Unused Sources of Power in Nature—such as the Tides, the Radiant Heat of the Sun, &c.; recent Improvements in Cable and Electrical Tramways; Mechanical Traction on

Digitized by Google

Common Roads; the Petroleum Engine and its Applications; the best Combined System of Warming, Ventilating, and Lighting large buildings; Electric Meters for recording the Consumption of Electrical Energy; the Construction and Maintenance of Secondary Batteries; the Application of Electricity to the Working of Cranes, Pumps, Tools, &c.; the Application of Electricity to Smelting and Metallurgical Operations; the Application of Electricity to the Purification of Water and of Sewage; the Purification of Copper, and the Reduction of Copper Ores by Electrolytic Processes.

Electric Alarm Advance Car.—A Mr. Harry Riesenberg, of St. Louis, Missouri, has devised an apparatus which he designates an "electric alarm advance car." Mr. Riesenberg proposes to send on in front of every railway locomotive a supporting car and pilot car. The pilot car receives its motive power from an electric motor thereon, which latter obtains electric energy through a cable from a dynamo on the locomotive. The pilot car is run at a higher speed than the train itself, and this keeps the cable tight and off the ground, and also propels the centre supporting car, which is attached to the cable midways between the front part of the engine and the rear end of pilot car. The cable contains, besides the wires for transmission of the current produced by the dynamo, also two wires which form an electric-bell circuit. If anything should happen to the pilot car the bell at once rings and warns the engineer. The same thing was, however, proposed last year by an Austrian engineer.

The Hussey Bluestone Battery.—This battery is an improved Daniell. The copper electrode is made in the shape of a thin circular disc, and is laid at the bottom of the cell. The porous jar containing the zinc electrode is glazed on its outside from top to bottom to render its sides non-porous, while the bottom being unglazed is porous. The jar is provided with legs, and rests on the copper disc. The outer jar is filled with copper crystals and solution to a little above its centre. The solution in the porous pot is kept at a higher level than that in the glass jar, consequently the pressure on the inner surface of the porous bottom is downward, so that the copper solution cannot get into the porous cup and come into contact with the zinc. The E.M.F. of the cell is 1·1 volts and its internal resistance is about ·22 ohm. It is claimed for this form of cell that there is absolutely no deposit of copper on the zinc, and amongst other advantages the zinc consumption is said to be very low.

Electricity in the Mine of St. Mauritius.—The following is extracted from the monthly report of the resident engineer:—"All is being arranged with a view to adapting water as a motive power in preference to steam, by which, latterly, the whole mine was worked at a great expense, both in the matter of skilled labour and in coal. The water will be collected in a large tank which will shortly be erected, and from this tank it will be conducted in wrought-iron pipes down the day shaft—a vertical fall of 260ft. to the turbine, which is already on the spot for erection. The positions for the turbine and the dynamo it drives are already determined, and the foundations, &c., are being prepared. With such a fall, with a plentiful water supply, the power of the turbine will be very great. The power of the dynamo will be transmitted to the pump shaft for pumping and winding purposes by means of cables and motors, supplied by Messrs. Immisch and Co., of London. Besides the above we shall probably have the advantage of electric light."

The Determination of Dielectric Constants by Means of the Telephone.—The specific inductive capacity of various substances have been determined by Winkelmann in the following manner:—Three insulated brass discs were arranged parallel to one another. The central disc had the same thickness as the two outer ones, but its diameter was one-half smaller. The outer discs were movable along a graduated support. The central disc was connected to one end of an induction coil, the other end of which was placed to earth. When the two outer plates were joined up through a telephone, there was a minimum of sound on the induction coil being brought into play whenever the central disc was equally influenced. The minimum was clearer the nearer the plates were together. Having determined the position of the minimum sound, a sheet of some dielectric substance was next interposed between the central disc and one of the outside plates, one of which was then moved until a minimum of sound was again obtained. If a is the distance of the two outside plates from the central disc before the introduction of the dielectric, and d is the thickness of this latter; D being its specific inductive capacity, and x the distance through which it was necessary to move the plate to restore equilibrium after the interposition of the dielectric substance, then we have $a - x = a - d + \frac{d}{D}$, whence $D = \frac{d}{d-x}$. In spite of the small error due to the difficulty of exactly determining when the minimum sound was given by the telephone, the results obtained for solid bodies and for liquids agree substantially with previous determinations.

The Edinburgh Exhibition.—On Saturday afternoon last the ceremony of cutting the first sod on the site of the International Exhibition to be held in Edinburgh next year, took place in presence of a large assemblage. Sir Thomas Clark said he believed that some people had an idea that this Exhibition had been introduced rather too soon after the Exhibition of 1886, but there had been very good reasons for it. They had promises from all parts of the world in this respect, and the little difficulties that were in the way with the London Chamber of Commerce had, he believed, all been got over, and now there would be a unanimous feeling throughout the whole of the electrical world that this Exhibition should be made a great success. The ceremony was then performed by Lady Clark. On Monday last there was a meeting at the Mansion House of the London Committee, recently formed in connection with the Exhibition. Sir George H. Chubb, the chairman of the London Committee, said it had been thought desirable to form that committee in connection with the Exhibition to give to those undertaking the arrangements the benefit of their advice and experience. Mr. G. E. Watson, the secretary of the Exhibition, said the guarantee fund amounted already to £23,000, and the buildings would cost £35,000 or more. The Exhibition would be open from May 1st to November 1st, and applications for space would be received until January 1st next. Mr. C. M. Kennedy, C.B., of the Foreign Office, moved a resolution commending the Exhibition to the support and co-operation of the public. The resolution was carried, and at the instance of Captain Shaw, C.B., a sub-committee for London was appointed, and the proceedings then closed.

National Telephone Electrical Society.—At the meeting of this Society on Friday evening, the 22nd inst., Mr. Arthur E. Cotterell, Vice-President, read a very interesting Paper on "Disturbances on Telephone Circuits." The Paper was illustrated with diagrams showing, *inter alia*, the various devices that have been adopted on telephone circuits with the object of minimising the effect of induced currents. Among the causes to which Mr. Cotterell assigned the disturbing effects experienced on telephone lines may be mentioned microphonic action due to unsoldered or "bad" joints, earth currents traversing the lines, induction due to adjacent earth plates, galvanic action, the result of using earth plates of dissimilar metal, and, of course, the ordinary induced effects due to currents from adjacent wires. Mr. Cotterell said he had found that in a cable, induction decreased almost in proportion to the number of wires in the cable having a "ground" connection at each end, from which he inferred that cables with as large a core as possible "earthed" at either end would be most suitable. A metallic earthed sheathing on the wires has a very beneficial effect. He relates a curious instance as worthy of further investigation, where the induction on two adjacent private wires was materially diminished by severing the pole earths. With regard to metallic circuits, he pointed out the useful effects derived from having a metallic sheath on the induction coil where a loop is joined to a single wire, and the necessity of keeping both arms of the loop line equally balanced to avoid the bad results recently obtained through one of the arms of the metallic circuit between Birmingham and the North of England having a bad joint. The Paper was a record of practical experiences, such as cannot fail to assist others in overcoming the many difficulties which surround the construction and maintenance of telephone networks.

ON THE DISTRIBUTION OF ELECTRIC ENERGY BY MEANS OF CONSTANT CURRENT.

BY ALEXANDER BERNSTEIN.

The energy of an electric current is the product of the strength of the current multiplied by the difference of potential at the ends of the conductor. Corresponding to these two values we have two general systems of electrical distribution—in the one the current, and in the other the difference of potential, is kept constant. Although a combination of the two systems is possible, such combination has so many difficulties, without apparent advantages, that we always employ the two simple systems. In both systems the incandescent lamp of normal candle-power is a characteristic feature. The system of constant potential requires lamps of high tension and small current, which are placed in parallel between the conductors. The system of constant current requires lamps of small tension and large current, which are arranged in series one after the other. The fundamental idea of the parallel system is the maintenance of a constant difference of potential between two conductors of electricity. As a matter of fact, this condition can only be fulfilled as long as there is no current in the conductors, but as soon as the current commences to flow we must necessarily have a variation in the tension on different parts of the line, a defect which can never be entirely overcome. This fundamental error in the theory of the system makes itself very much felt as soon as we have to deal with larger plants. In order to obtain an approximation to constant potential in the conductors under varying loads and long distances, we are forced to make use of a complicated and expensive system of conductors, and of a variety of arrangements for regulating the tension, which require constant supervision. The large number of proposals which have lately been brought forward in order to overcome this difficulty in the system of constant potential, show very distinctly that the problem has not yet received a satisfactory solution, which is not surprising, as a complete solution is a matter of impossibility. The use of incandescent lamps in parallel requires constant potential, as a small rise in potential between the two conductors very materially affects the life of the lamp, and a decrease reduces the light considerably, although the consumer has to pay about the same price as for a full candle-power lamp.

It is totally different if we have a system worked on the principle of constant current. Here the fundamental idea is theoretically correct, and is capable of being carried out in practice, entirely independent of the distance which we have to overcome. The practical advantages of such a system have induced me (already in 1882) to turn my special attention to this matter, and it is the purpose of this Paper to describe the system, as worked out by me, in its present state.

I shall commence with the description of a simple circuit in which glow lamps are placed in series, such a circuit as shown in Fig. 1. In this figure the steam-engine A is shown driving a dynamo B, the conductor is marked C, and in this conductor the glow lamps D D are placed one after the other. Now, the first condition in the case of such a system is the maintenance of constant current independent of the resistance of the circuit; that is, independent of the number of lamps in use. The fulfilment of this condition appeared at first to offer considerable difficulties, which were, however, overcome in a very satisfactory manner. Constant current on the line means variation of E.M.F. in the dynamos according to outside resistance. Now, the E.M.F. of a dynamo can be varied in several ways—for instance, by variation of the magnetic field, or by altering the position of the brushes; but both these methods have their defects, and especially the latter, which is open to many objections. The much better way of altering the E.M.F. consists in varying the speed of the dynamo, and this method contains advantages which cannot be obtained in any other way. If a series dynamo is driven by a steam-engine from which the centrifugal governor has been removed, then this combination has in itself a tendency to produce constant current on the line; this means the steam-engine will run fast if there are many lamps on the circuit, and will reduce its speed if the number of lamps is reduced. To most engineers this always appears so singular that I shall explain the action in a few words.

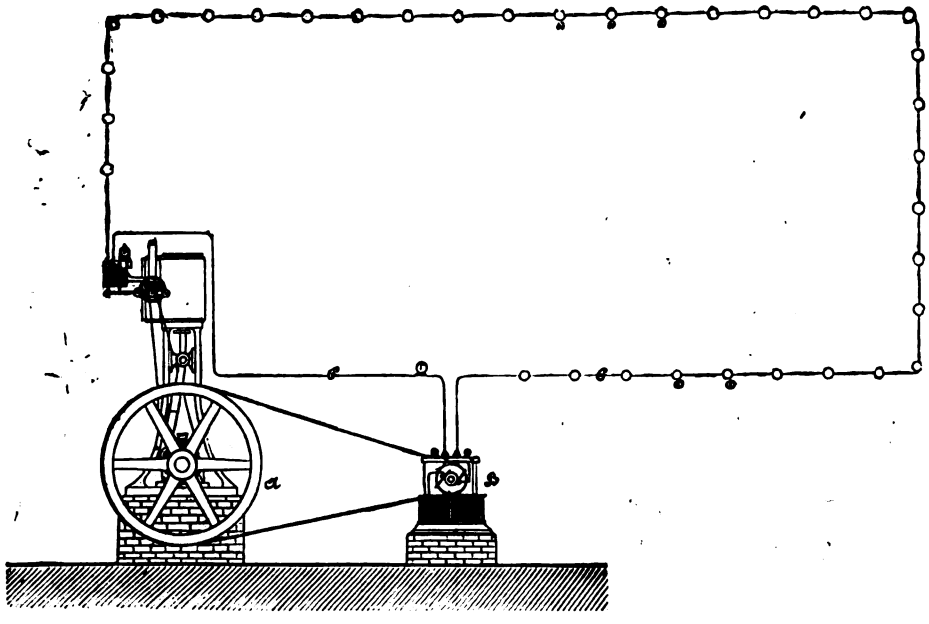

FIG. 1.

We are dealing here with a dynamo which has a field of constant intensity, and under these circumstances the E.M.F. and therefore the current produced is equal; outside resistance is simply dependent on the number of revolutions of the armature. The strain on the belt which is necessary to maintain the armature in rotation is dependent on the current, and quite independent of the E.M.F. This strain is produced by the pressure of the steam; therefore, if the steam pressure is given, the strength of current in the armature is determined which will counterbalance this pressure on the piston. I shall suppose that a state of equilibrium is maintained if the steam-engine makes 100 revolutions, and the current is equal to 10 amperes. Now, if lamps are added, the outside resistance would increase, and therefore the strength of the current would be diminished. This has the effect of disturbing the equilibrium; the current is too weak to counterbalance the steam pressure, which we assume is constant, and the engine commences to move faster until equilibrium is again produced; this is as soon

Digitized by Google

as the current has again reached 10 amperes. The reverse would take place if we diminish the number of lamps on the circuit. If we, therefore, use a steam-engine without centrifugal regulator, driving a series dynamo, we can obtain constant current in the circuit, provided that the steam pressure in the cylinder remains constant. This method of regulation was first put to practical use by me about three years ago, and has since then been adopted by others. As, however, the pressure in the cylinder cannot be relied upon as constant, and as this pressure, moreover, varies with the speed of the piston, it becomes necessary to use an electric regulator, in order to correct the irregularities in current which would otherwise result. I shall first describe the construction of the regulator which I am now using.

The regulator, Fig. 2, contains a well-balanced steam valve moved by a spindle, which carries the friction wheel A. A small rope pulley, B, is situated underneath the shaft of the friction wheel A, and this pulley is kept revolving from the shaft of the engine. The shaft of pulley, B, carries a lever, C, which contains the bearings for two small pulleys, D and E. These pulleys are connected in such a way with B that one is driven by an open, the other by a crossed belt. Small friction rollers are attached to the pulleys D and E, and, according to the position of the lever C, these rollers may come into contact

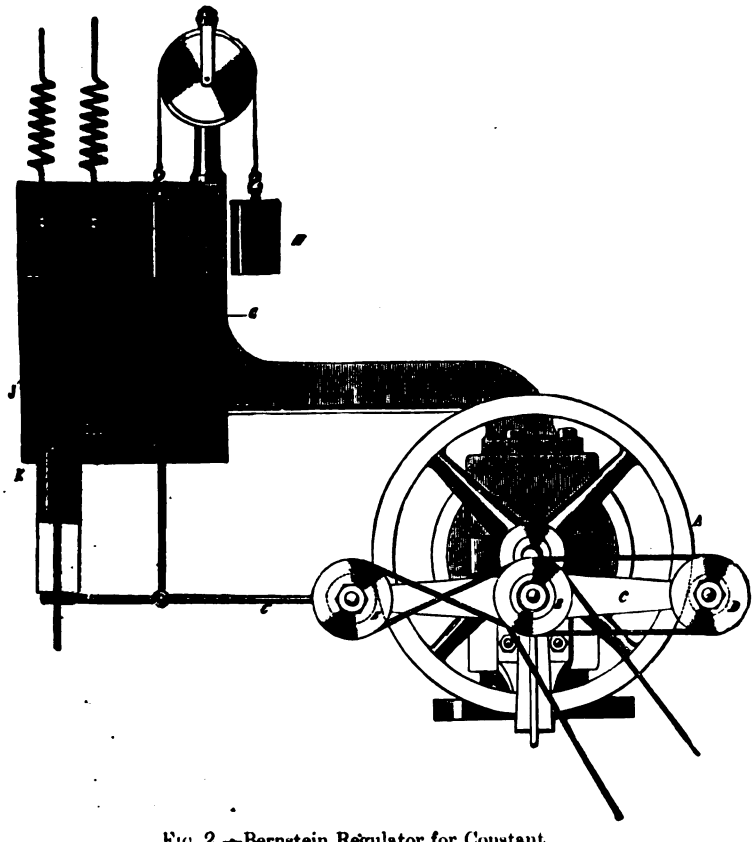

Fig. 2.—Bernstein Regulator for Constant Current Working.

with the wheel A. The position of the roller depends on the position of the iron core F, inside the solenoid G. The current which is to be regulated passes through this solenoid, and the counter-weight H is adjusted in such a way that the lever C is held in a horizontal position if the current has the normal strength. If the current were to increase, the iron core would be drawn further into the solenoid, the friction roller D comes into contact with A, and the opening of the valve is reduced until the normal strength of current is again established. The reverse takes place if the current becomes too weak, in which case the friction roller E is brought into action. It will be noticed that the power necessary to move the valve is supplied by the engine, the current merely directing the force. As the engine has no centrifugal regulator, it is necessary to prevent its running away if a belt should break, or the current be otherwise interrupted. For this purpose the regulator contains a second solenoid, J, with fixed iron core, which carries the weight K, if the current has approximately the normal strength, but if this current is interrupted the weight drops and rests on the lever C, the friction roller D comes into contact with A, and the valve is closed by the engine. I might remark that the falling weight has to my knowledge been first used by Messrs. Robey and Co. I mention this fact in order not to produce the impression that I claim priority on this point. The regulation by means of varying the speed of the engine is not only perfect, but it presents advantages in regard to economy which cannot be obtained in any other way, This method is only applicable to a system of constant current; if it is desired to maintain constant potential, the speed of the engine has to be kept nearly uniform. Now this has the disadvantage that we are only working economically if the engine is exerting its maximum power. With a certain steam pressure there is a certain degree of expansion at which the consumption of coal

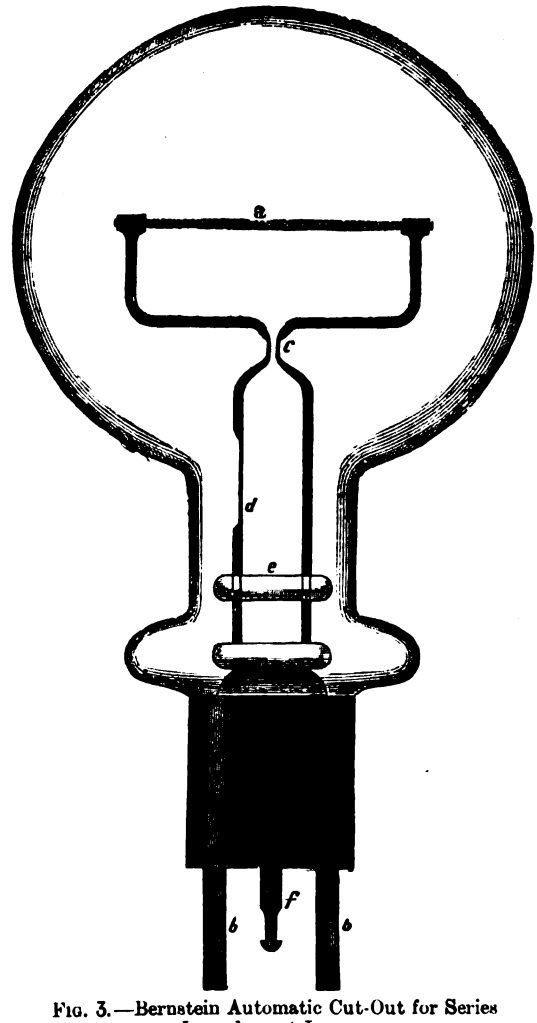

Fig. 3.—Bernstein Automatic Cut-Out for Series Incandescent Lamps.

is a minimum. If we use this highest degree of expansion when the engine is doing its maximum work, we are often working against the pressure of the atmosphere if we reduce the power of the engine. Very different in the above mentioned method of regulation: the velocity alone varies, the advantage of the expansion always remains the same. A steam-engine of 100 horse-power consumes 15—20 horse-power in order to run at full speed without doing any useful working. This means 15 per cent. loss at full power, 30 per cent. at half power, &c.; in fact, all motors are very uneconomical if they have to maintain full speed without doing maximum work. A gas-engine, for instance, consumes at half load five-sixths of the amount of gas which is required at full load. Lastly, the wear and tear remains about the same as long as the speed is the same; but if we adopt the method of varying the speed, the internal work and the wear and tear is about in proportion to the useful work,

Digitized by Google

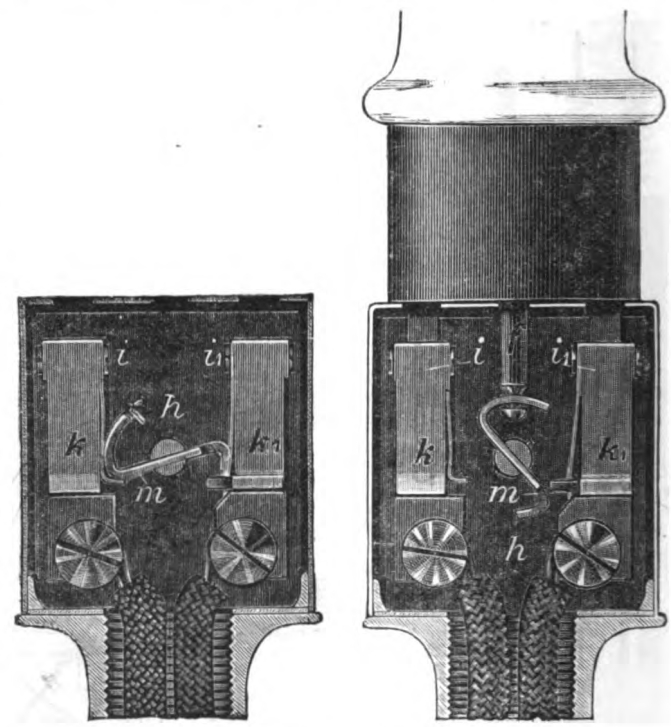
and we therefore secure an advantage which cannot be obtained in the system of constant potential. The construction of the dynamo offers no special difficulty; we have indeed to deal with the simplest conditions. The current in the field-magnets and the armature remains constant, and under these circumstances the position of the brushes on the commutator never requires any alteration. This is a very important feature of the system. In fact, the further development of the system, of which I shall speak later on, would hardly be practicable without this peculiarity of the dynamo.

If I now turn to conductors, I arrive at that part of the series system which many electricians generally consider as the only advantage of it, but I believe this Paper will show that the possibility of overcoming long distances with small conductors is only *one* of the practical advantages of the distribution of electrical energy by means of constant current. It is well understood that the expense of conductors in a series system is much below that required in a parallel system. To give an example: Supposing 100 lamps each consuming 60 watts have to be supplied with electrical energy at a certain distance from the dynamo; the lamps placed in parallel are to be each of 100 volts and .6 amperes; the lamps in series requiring 6 volts and 10 amperes. In this case the cross-section of the conductor for the parallel arrangement would have to be 36 times larger than that required to be used in the series arrangement, if the same loss of energy is to be allowed in the conductors. But, quite independent of the cross-section, we can in the latter method always maintain constant current, independent of the number of lamps in use and the distance, while the difficulty of maintaining constant potential increases materially with the distance. There is another advantage which is peculiar to the system of constant current, and this is—that there can be no over-heating of wires, and therefore safety fuses are dispensed with. The necessity of using safety fuses in order to guard against the danger of fire is one of the great drawbacks of the parallel system. Every electrician of experience has known cases in which whole groups of lamps have been extinguished by the melting of a fuse; or, what is still worse, fuses are sometimes replaced by copper wires with the idea of putting the proper fuse in place later on. In this case the danger of fire is always present. A system which can dispense with the use of fuses has certainly a considerable practical advantage.

In turning now to the lamps, I arrive at that part of the system which has caused more difficulty than any other, and which has required years of experimenting. In the manufacture of incandescent lamps, we are obliged to confine ourselves within certain limits as far as the size of the carbon is concerned. If the carbons are made for very high tension and corresponding small current, we reduce the efficiency on the life of the lamps; if, on the other hand, we use very thick carbons for strong current, the difficulty rests in the connection of these carbons with the leading-in wires and the seat of the platinum wires through the glass. Experience has shown that 10 amperes is about the maximum current for lamps in series. As the carbon in every lamp is subject to deterioration, we must provide for means to prevent interruption of the circuit by the breakage of the carbon, if the lamps are arranged in series. The first apparatus which I used for this purpose, in 1883, was actuated by means of an electro-magnet; but the size and the high price of this apparatus induced me later on to construct the chemical contact-plug. Lately, however, I have succeeded in constructing the lamp in such a way that the simplest arrangement of self-acting cut-out is placed within the lamp itself.

The construction of the lamp as now made is shown in Fig. 3; *a* is the light-giving carbon made in the form of a straight rod. The ends of this rod are attached to two nickel wires, which are soldered to the platinum wires which convey the current through the glass. The two nickel wires are bent in such a way as to almost touch each other in *c*, and one of the wires, *d*, is hammered flat so as to form a spring, which has the tendency to produce contact in *c*. This, however, is prevented by the carbon itself as long as the carbon is intact. If now the carbon becomes deteriorated by the current, it gives to the pressure of the spring, and contact is made in *c*. This simple arrangement has, moreover, the great advantage that the production of an arc inside the lamp is entirely avoided. Such an arc is often formed in lamps placed in series, if the action of the cut-out is dependent on the increase of resistance of the lamp, and the heat of the arc is very liable to crack the glass. The arrangement described above effectually prevents the arc. Constructions in which the heat of the arc is utilised for the purpose of making a cut-out, or which are based on the supposition that a high-tension current will always find its way round the lamp through a weak insulation, in case the carbon should break, can hardly be considered as practical solutions of the problem.

It is now generally acknowledged that lamps with thick carbons give a better conversion of electrical energy in light than lamps with fine carbons. Generally, we must suppose that the destruction of the carbon in the lamp in which there is a high difference of potential results from the combined action of the heat and current. Heat has the effect of diminishing the cohesion, and the electrical forces produce motion of the carbon particles from the negative to the positive pole. This process is well known in lamps of high tension, but in lamps which are required in the system of constant current, the difference of potential is so small that no destructive electrical action can take place. There is another cause which has the tendency to diminish the economy in lamps which have very thin carbons, and this is that the cooling effect of



Figs. 4 and 5.—Bernstein Incandescent Lamp Holder.

surrounding gases which may be contained in the lamp is far more perceptible here than in lamps with thick carbons. The heated carbon loses its energy in several ways, namely, by radiation, by direct convection to the surrounding gases, and by conduction of the heat to the leading-in wires which are connected to the carbon. I shall, for the present, neglect this last point. The radiation only depends on the temperature, the surface, and the quality of the carbon, but is independent of the diameter. On the other hand, convection to surrounding gases is far more marked in fine carbon than in carbons of large diameter. In a series of experiments which I have made on this point, I found that a glowing wire of ·09 mm. diameter consumes two and a-half times more energy in the atmospheric air in order to be kept at the same temperature than a wire of ·26 mm. diameter. Of course, this difference would disappear in an absolute vacuum, but as we are hardly likely to maintain a very high vacuum in the lamp, the effect is that there is practically always a considerable difference in favour of thick carbons. The nature of the surface has a great deal to do with the efficiency of the lamp, because the proportion of heat radiation to light radiation at the same temperature

Digitized by Google

materially depends on the nature of the surface. Experiments have shown that a smooth surface is highly conducive to increase the light radiation. The strong hollow carbons which are used in glow lamps for series lighting have made it possible to obtain in them a very smooth surface by using a mechanical process of polishing the carbon; such a process is, of course, not applicable in the fine twisted carbons used in lamps of high resistance. For the purpose of supplying light from central stations, the peculiarity that lamps for strong currents give a much higher effect than can be obtained from lamps of high tension and small current is, of course, of the greatest importance, as this results in materially reducing the price of electric light. There is another point in favour of the straight thick carbon rod, as compared to the fine twisted thread, which merits consideration. These latter produce a disagreeable irritation of the eye, whenever we look from the heated carbon into the dark, when the impression of the bright thread is retained on the eye. This is not the case with a straight carbon rod; and in all places in which both kinds of lamps have been in use, I have been assured that the straight carbon rod is much preferred as a light-giving body, especially by persons with sensitive eyes.

The construction of the lamp requires the application of a specially-constructed holder, which is illustrated in Figs. 4 and 5. Two metal sleeves, into which the square terminals *b b* of the lamp are made to fit, are attached to an insulating plate, *h*. The outward part of these sleeves is replaced by the springs R R_1, which insure good contact by pressure of the terminals against the metal sleeves. A piece, *m*, in the form of an S, can be turned by a handle. In the position of this piece, shown in Fig. 4, the current is short-circuited inside the holder. The flat spring K_1 carries a small steel pin, which in the position shown prevents the piece *m* from being turned, so that the circuit cannot be opened. If, now, the lamp is placed in the holder, the spring K_1 is slightly lifted, in such a way that the pin is now outside of the level of *m*. This piece can now be brought into the position shown in Fig. 5, when the lamp will be alight. However, as long as this is the case, the lamp cannot be removed from the holder on account of the piece *f*, which is fastened to the lamp cap, and which is now held in place by *m*. If it is desired to remove the lamp from the holder, the current must first be short-circuited in the holder by turning *m* again into the position shown in Fig. 4. It is therefore clear that any interruption of the circuit is effectually prevented. If I now add that if every circuit is provided with an ammeter, and that switches of well-known construction are used for extinguishing groups of lamps, I have fully described a simple series circuit.

(To be continued.)

UNDERGROUND CONDUCTORS.

BY DAVID BROOKS.

Conduits for underground electrical conductors are generally supposed to facilitate the construction and repairs of an underground system; but, in my opinion, such is not the case, as I will endeavour to show. Nothing that is drawn in can long withstand the damp and confined atmosphere of a conduit, mixed as it is with sewer and illuminating gases. If the conduits are made of wood, the acid coming from the wood itself contributes to the process of disintegration and decay. When a cable or conductor in a conduit fails, in nine cases out of ten there are no cables or conductors ready to supply the place of the one pulled out, and it is necessary to wait for one to be manufactured. This is the "draw in and draw out" system.

The Edison system is different. The faulty conductor cannot be pulled out and replaced by another; but the fault, when it occurs, is local, and can be located to an inch, and remedied in as short or less time than it takes to get ready to pull a cable of 500 feet in length out of a conduit. The Edison Company in Philadelphia have located and removed or repaired over 300 faults, due to original bad construction rather than to the system itself. The locating of faults with such exactitude is effected by the "loop-test." Faults in ocean cables are located by this means within a few miles. In ordinary city limits they are located within a few feet. When it comes to the distances between splice-boxes or hand-holes, the defect can be located to an inch.

The system with which I am identified is a draw in but not a draw out system, for the reason that there has been no occasion to draw out. If the insulation is impaired or destroyed, it must be from mechanical means, such as breaking or injuring the wrought-iron pipe, which is proof against an accidental blow of the picks. The pipe is placed so far below the surface of the ground as not to be disturbed in ordinary street repairs. The material within the pipe is hermetically sealed from such agencies as destroy gutta percha, indiarubber, or anything else that is of the vegetable kingdom. The oil we use in the pipe is a pure distillate, and no product of distillation undergoes change, except for the better, when confined in air-tight vessels. Thus there is no deleterious change. As before stated, the Brooks method is not a draw out system, for the reason that there is no necessity to draw out. But a thousand feet of cable can be drawn out easier than five hundred feet could be drawn from any conduit system, because the former is lubricated inside the pipe. If perchance the insulation becomes impaired, as stated, it must be from some damage done to the pipe serious enough to expose the conductors, as a mere hole in the pipe will not admit moisture, because the oil is much heavier than water. The defect must be local, and its position can be readily determined, as before explained. A pipe-cutter, with a few feet of cotton-covered wire, can easily repair the damage. On the other hand, when a fault is detected in a cable that has been drawn into a conduit, every portion of it shows serious disintegration. If a cable on my system is injured by mechanical means, the surface of the ground must be disturbed, which would be enough to indicate the exact position of the fault, without the aid of the loop-test.

The effect of confined air, such as is contained in a conduit, has been known in England for at least thirty years. A patent was taken out to preserve the gutta-percha covering on conductors by drawing the cables into iron pipes filled with water. The English Post Office department do this yet wherever it is practicable.

Telephone exchanges require large numbers of conductors of small diameter. Five hundred of these conductors properly insulated can be drawn into a three-inch pipe, when oil is used. These conductors generally take one direction in getting from the basement of the exchange into the street. Suppose for that purpose a single pipe of large diameter is used: for instance, one of 15in., the ends of the pipe being bent upwards in order to prevent the loss of oil—this pipe would have a capacity for ten thousand conductors, which could be drawn into the oil in groups of one hundred. I know of no method by which the insulation could be so well preserved. Now compare the cost of such an arrangement with the conduit system. Ten times as much money is spent in making a poor job as is necessary to make a good one. When once in the street, the conductors would diverge and take opposite directions. Then two or more pipes of smaller dimensions could be used. Such a plan could be adopted as would accommodate the number of wires as they diverge in different directions. Again, compare the cost of such an arrangement with that of some of the subways that have been constructed in New York City. Philadelphia has more electrical conduits than all the other cities of the United States. There are as many as four in some of the streets. There are, however, very few conductors in them, but a new industry has been developed: that of keeping the subways in repair—pumping water from the man-holes, cleaning them from the dregs of the sewers that have been broken open, and their contents deposited in the ducts. In some cases the water mains have broken and filled the conduits with water, producing washouts and caving in of street pavements. Rotating fans are used to clear the conduits of the explosive gases, which also produce death by suffocation, nearly as instantaneous as that produced by the arc light currents in New York City. We have had over 50 explosions in Philadelphia. I have this on the authority of one of our best-posted electric light engineers. Most of our conduits are made of wood, and the explosions, as a consequence, do not reach the magnitude of

Digitized by Google

some that have occurred in Broadway, New York, where, according to the reports in the New York papers, a cast-iron man-hole cover, weighing 300lb., was thrown over a four-story building. The ducts of these conduits are made of wrought iron. Conduits are expensive, and their construction a slow process, which interferes with the use of the streets. Large quantities of earth have to be carted away. With the Brooks system, the iron pipe occupies so small a space that all the earth taken out is repacked in the trench. Ten thousand feet of trench have been opened, the pipe laid, the trench closed, repaired, and cables drawn in, between seven in the morning and six o'clock in the afternoon of the same day, and no patching or levelling up of pavement required afterwards. It is stated that in laying conduits extra ducts can be provided for future growth of business. By the Brooks system extra conductors, or a cable containing more conductors than required by the present need, can be drawn in by the one operation. By the Brooks' system there are no vacant spaces for the collection of explosive and deleterious gases.

In proof of what I say, it goes for something that the cable I laid for the Pennsylvania Railroad Company, containing 53 conductors, has worked for nearly three years without a moment's interruption to any of the conductors, although connected to overhead wires running to New York, Pittsburgh, and Washington. There has been no expense for repairs and maintenance except to paint those portions of the pipe running over a bridge and along an elevated railway.

THE BIRMINGHAM EXHIBITION.

We this week conclude our notices of the Birmingham Exhibition with descriptions of the exhibits of Messrs. Immisch and Co., the Electric Construction Corporation, Messrs. Appleby, Burbey, and Williamson, Messrs. Crossley Brothers, and the Campbell Gas Engine Company.

Immisch and Co.—Messrs. Immisch exhibited a number of motors and dynamos of the types for which the firm have become famous. A 2-horse mining-type motor was made to drive a ½-horse dynamo, which supplied current to a 2-horse motor running light. The mining-type motor was of the same type as the larger machine which has been in operation at St. John's Colliery, Normanton, since February, 1888, and which has been running about 22 hours per day up to the present time. The next object of interest was a tramcar motor, similar to those fitted to the cars on the Barking and Canning Town tramways. The motor was of the type in which the armature rotates between two vertical field-magnets, which are joined at both ends by castings forming the pole-pieces; it is designed to develope 10 horse-power when running at 1,000 revolutions, and requires a current of 68 amperes at 160 volts E.M.F. The motor exhibited was fitted with an ordinary pulley, but when employed for car driving this is replaced by a spocket wheel for chain gearing. A constant-current series motor of the vertical magnet type, to develope 3½ horse-power, was also exhibited. In this machine the regulation was effected by means of a very compact centrifugal governor, which was fitted on the end of the shaft. The centrifugal arrangement operates a sliding connecting bridge, which makes the connection between the two field-magnet windings. The coils of the magnets are wound in a number of sections, and connection is made at a point between each section to a number of insulated plates, the plates connected with corresponding parts of the magnet coils being opposite each other. The sliding bridge, in making connection between a pair of these plates, short circuits an equal number of sections on each magnet limb, and the number of ampere turns is thus varied in conformity with the variation of load or E.M.F., as the case may be. Messrs. Immisch also supplied the motors to some of the exhibitors who were using power on their stands.

The Electric Construction Corporation (Limited).—This company exhibited a battery of 27 of their B 31 type storage cells, which were employed to light the dining rooms. The total capacity of the cells, as given by the makers, was 700 ampere-hours. During the Exhibition the daily requirement amounted to 329 ampere-hours per day, with a maximum rate of discharge of 87 amperes, which occurred regularly for one and a-quarter hours per day. The charging current was 60 amperes, and was maintained for six hours each day, or a total of 360 ampere-hours' charge. This shows a *current* efficiency of 91½ per cent. The condition of the battery appeared to be perfect in every respect. This company also exhibited a burglar alarm, adapted for houses having a 50-volt circuit at command, but which can, of course, be arranged to work with current from any source of sufficient power. The point of interest about this alarm is the arrangement by which a reciprocating motion is obtained. A glance at Fig. 1 will explain this. *a* is an iron core, which is fitted at each end with a lengthening piece of brass, which carries a small steel striker fixed in its end: the striker strikes the bell (indicated by dotted lines) at opposite points in alternation; *b b* are two coils, of

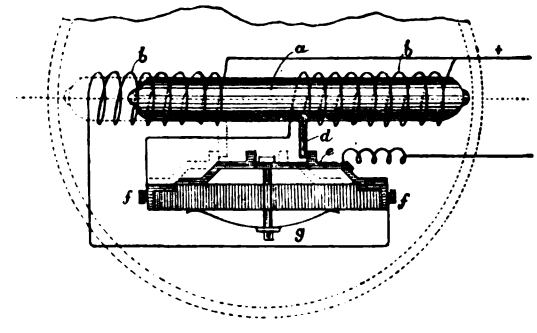


Fig. 1.—Burglar Alarm for House with a 50 volt circuit.

which one end of each is connected permanently to one pole of the exciting circuit, and the other two ends are connected to insulated plates, *f f*. The iron core carries a projecting pin, *d*, which engages towards the end of each stroke with one or other of the projecting lugs on the sliding connector *e*. The other pole of the exciting source is connected by a flexible lead to the sliding connector. When the core is pulled up to one end by the action of the current in one coil, the sliding connector cuts off connection with this coil and makes connection with the other, and a reciprocating motion is the result. In the alarm exhibited the coils *b b* have a resistance of about 60 ohms.

Appleton, Burbey, and Williamson.—This firm exhibited their patent adjustable switches, an illustration of which we give below (Fig. 2), also a very simple and well-designed

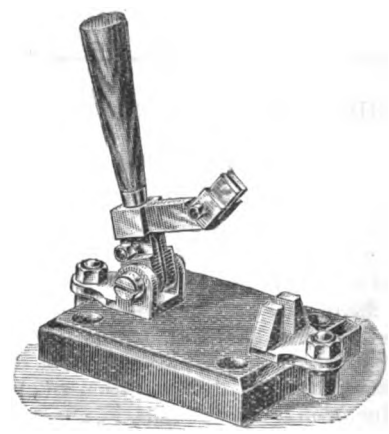

Fig. 2.—Adjustable Switch.

automatic switch for use with accumulators (Fig. 3). When the battery is not being charged, the balance lever is held down by the weight at the end, and the circuit through the coil is completed by means of the mercury contact. The coil is a shunt on the dynamo terminals, and the weight on the lever is so adjusted that the iron core which hangs in the coil shall be attracted with sufficient force to lift it when the E.M.F. is sufficiently high for the battery to be connected on

Digitized by Google

for charging. When the lever lifts up, the charging circuit is completed by means of the mercury contacts on the other end of the lever, and the shunt-circuit is broken. An electro-magnet whose coil is in the charging circuit comes into action when the circuit is completed, and maintains the connection so long as the charging current does not fall below a minimum value. If this occurs, the charging circuit is broken and the shunt circuit re-made, and the contrivance is ready to switch the battery on as soon as the E.M.F. has again reached the required value for charging.

This firm also exhibited teak boxes for accumulators, which were made acid proof by means of a thin liner of celluloid material.

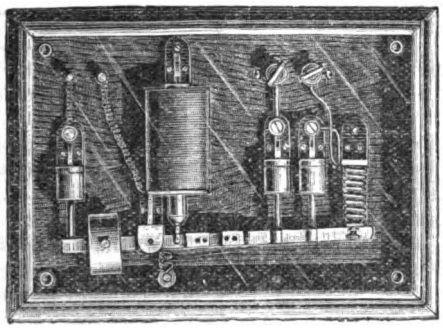

Fig. 3.—Automatic Switch for use with Accumulators.

Crossley Brothers.—This firm exhibited their newest form of gas engine suitable for running electric light installations; a 3 horse-power vertical engine, speeded up to 250 revolutions, was driving an Elwell-Parker dynamo, from which the stand was lighted by means of fifty 16 candle-power lamps. A 4 horse-power horizontal engine also drove an Elwell-Parker dynamo, which was employed to charge the battery of 31 B type cells, from which the dining rooms were lighted. These engines were fitted with the tube ignition and Messrs. Crossley's new timing valve. With a tube ignition in its simplest form there is a possibility of the charge being ignited before or after the proper time; the timing valve is designed to obviate this danger. Fig. 4 represents a section through the timing

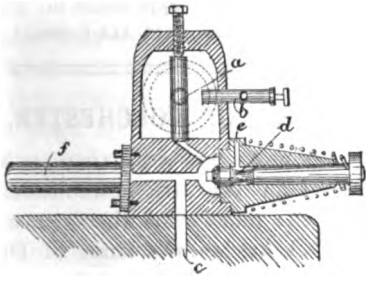

Fig. 4.—Section of Timing Valve fitted to the Otto Gas Engine.

valve of a vertical engine: *a* is the end view of the ignition tube which stands up perpendicular to the paper in the drawing, *b* is the Bunsen burner which maintains the tube at a red heat, *d* is the valve, *e* is a small opening to the outside air, *f* is a small closed chamber in connection with the gas ways, *c* is the passage which leads iuto the cylinder. The valve is shown in the position which it occupies at the moment when the charge is to be ignited. The compressed charge enters from the cylinder by the pasage *c*, fills the small chamber *f*, and passes through the passages into the ignition tube and is ignited. A cam now presses the valve *d* inwards (against the spiral spring), the point of the valve closes the passage into the cylinder, while the gas and air in the chamber *f* insure the maintenance of the flame and the proper ignition of the charge; at the same time the valve *d*, having a clearance cut on the parallel part just below the valve, connects the small outlet *e* with the ignition tube, and thus gives it an independent exhaust. These combined arrangements make the ignition of the charge at the proper instant an absolute certainty. The ignition tubes of these engines require renewal about every five or six days, as they become oxidised right through and choked completely with gas carbon in this short time. The cost of the tubes is trifling, and they are readily replaced.

The "Campbell" Gas Engine Company (Limited).—This company exhibited a 4 horse-power engine, which drove a dynamo, from which the stand was lighted by means of 16 candle-power lamps. This engine has an impulse every revolution, which is secured by the employment of a pump in addition to the working cylinder. There are very few valves about this engine, and its cycle of actions is extremely simple, and is as follows:—The pump piston on the out-stroke takes in a charge of air and gas, and on the return stroke compresses it; in the same time the working piston has reached the limit of its out stroke, and the exhaust ports—which are in the sides of the cylinder at the front end—being uncovered by the piston, the exhaust gases escape; when the pressure in the working cylinder is thus removed, the new charge which is compressed in the pump cylinder opens a valve, and passes into the working cylinder. The working piston now returns and compresses the charge, a portion of the mixture reaches the red-hot part of the ignition tube, and the impulse takes place. The engine is fitted with a very simple governor.

Messrs. Barker exhibited two gas engines, one with their patent rotary valve, which was so highly spoken of by Prof. Smith in his report of this engine, and the other with a tube ignition. The engine with tube ignition drove a Stafford and Eaves dynamo.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To night) FRIDAY, November 29th.

Institution of Civil Engineers.

7:30 p.m. Students' Meeting. Paper to be read, "Principles of Iron Foundry Practice." By G. H. Sheffield, Stud.Inst.C.E.

Electro-Harmonic Society.

8 p.m. Concert at St. James's Hall Restaurant, Regent Street. (Ladies' night.)

MONDAY, December 2nd.

Royal Institution.

5 p.m. General Monthly Meeting.

London Institution.

5 p.m. Lecture: "The Growth of Crystals in Rocks." By Prof. J. W. Judd, F.R.S.

Society of Engineers.

7:30 p.m. Ordinary Meeting. Paper to be read, "Fox's System of Solid Pressed Steel Waggon Frames." By Perry F. Nursey, Past President.

Society of Arts.

8 p.m. Cantor Lecture I. 2. "Modern Developments of Bread-Making." By William Jago.

TUESDAY, December 3rd.

Institution of Civil Engineers.

8 p.m. Ordinary Meeting. Paper to be further discussed, "Water-Tube Steam Boilers for Marine Engines." By Mr. John J. Thornycroft, M.Inst.C.E. Paper to be read, time permitting, "On the Triple-Expansion Engines at the Owen's College, Manchester."

Royal Victoria Hall.

8:30 p.m. Lecture: "Snakes and Snake Poison." By Dr. W D. Halliburton, M.R.C.P.

WEDNESDAY, December 4th.

Civil and Mechanical Engineers' Society.

7 p.m. Meeting at the Westminster Palace Hotel. Opening Address by the President, Henry Adams, M.I.C.E.

Society of Arts.

8 p.m. Ordinary Meeting. "Rabies and its Prevention." By Armand Ruffer, M.A.

THURSDAY, December 5th.

London Institution.

6 p.m. Lecture: "Recent Work on Moulds and Mildews." By Henry Power, M.B.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

GILBERT, OF COLCHESTER.

Just as we go to press this week there is being held the inaugural meeting of an Association established to do honour to the memory of the founder of the science of electricity. Although to every electrician the name of Dr. GILBERT, of Colchester, is more or less familiar, the outside public is strangely ignorant both of the man and of his claims to a niche in the roll of the worthies who have made England famous. What SHAKESPEARE is to the drama, what RALEIGH is to geography, what SPENSER is to poetry, what BACON is to philosophy, that, and more than that, is GILBERT to the science of electricity. Born at Colchester in 1540, and educated at St. John's College, Cambridge, of which he was a Fellow, he embraced the profession of medicine, travelling much abroad in the prosecution of his studies. Great distinction awaited him, and he rose to the summit of his profession, becoming in 1599 President of the Royal College of Physicians. He had for some years been physician in ordinary to Queen ELIZABETH, and at her decease in 1603 was continued as physician to JAMES I., an honour cut short by GILBERT'S death in November the same year. His fame, which even before this extended throughout Europe, was based, however, not upon his medical distinctions, but upon his experimental studies in magnetism. Living alone, and possessed of adequate means, he expended, as is recorded, no

Digitized by Google

less a sum than five thousand pounds upon his researches, and amassed a fine collection of loadstones and magnetic apparatus, globes, charts, instruments, books, and manuscripts. Even before he had published a single line of his researches, the fame of them had gone abroad through the scientific men in the various universities of Europe. At length, in 1600, appeared his famous book, "De Magnete," a fine folio volume of two hundred and forty pages, the Latin text printed in bold Dutch type by PETER SHORT, of St. Paul's Churchyard, and illustrated with numerous primitive woodcuts of his apparatus and experiments. The book was of a sort wholly novel and strange, even to the learned men of that time. Men still lived in the shadow of mediæval modes of thought, and were accustomed to have all scientific facts wrapped up in a portentous metaphysical jargon, in the manner of the disputations of ST. THOMAS AQUINAS, and embroidered with a fringe of magic and mystery, teeming over with erudition and speculative philosophy. To men steeped in such literature it was quite incomprehensible that valuable scientific facts should be discovered by the simple device of actually trying experiments; quite inconceivable that any one with the reputation of being a philosopher should set them down in plain unvarnished fashion, without attempting to explain them by occult disquisitions showing their relation to the mysteries of the universe. And, that such an individual should have propounded the insane notion that the earth itself was a great magnet, in order to explain why compass needles pointed northwards—why, was it not known that the great PARACELSUS had reported that the compass pointed northwards by reason of the virtue proceeding forth from the stars in the constellation of the Great Bear? And had not the immortal CARDANUS located that virtue in the particular star at the tip of the Great Bear's tail? And, if that was not explanation enough, had not MAUROLYCUS discovered in the great North Sea a magnetic island which would even draw the iron nails out of the passing ships, and was not its position set down in the charts of PLANCIUS? Why then should they listen to the new doctrine that the earth was itself a magnet, on the mere suggestion of a man whose philosophy began and ended with experiments made on little loadstones? Nay, worse than this, it was unendurable that the man who had so abused his position as a philosopher as to condescend to a purely experimental method should turn round and poke fun at the philosophers for their stupid magic and their senseless mystery, and curse them for darkening knowledge with words.

Accordingly we find that the appearance of "De Magnete," though it won the admiration of GALILEO, and secured the enthusiastic adhesion of KEPLER to the new doctrine of the magnetism of the earth, was derided by the wordy philosophers of the day, such as SCALIGER, and even by BACON, whose claim to be regarded as father of the experimental method is based on writings of fifteen years' later date.

To us, as electricians, however, the main interest in Dr. GILBERT centres around a single short chapter in "De Magnete," where he steps aside for a moment from the immediate subject of the magnet to discuss the attraction excited by amber that has been rubbed. This fact, discovered at least 500 years before the Christian era, had remained an isolated fact, save only for the knowledge that jet shared a similar property. Concerning amber, as concerning the loadstone, there had grown up a luxuriant crop of fabulous mysteries. These, too, went down by a touch when the master-hand of GILBERT applied the test of the experimental method, and showed that not alone amber but a vast class of bodies, which he termed electrics, including the diamond and other gems, paste gems, glass, shellac, resin, mastic, and the like, possessed similar powers of attracting. To test their power he devised a simple electroscope. He discovered the adverse influence of moisture, and the screening action of an interposed sheet of metal. Not without some blunders, he pushed his way into the region of the unknown, and stopped short all too soon. Not too soon, however, to make good his enduring claim to the distinction of being the first electrician; the spiritual father of the Guerickes, the Boyles, the Hauksbees, the Stephen Grays, and the Franklins who followed along the path he had trodden alone. Nor do his claims on posterity end here, for he founded a "college," or society, which used to meet periodically at his house in Peter's-hill, Knightrider-street, to discuss philosophical subjects, of which "college" the Royal Society is the legitimate successor. That he has been so little honoured with the wider fame that attaches to his great contemporaries is due doubtless to the circumstance which has robbed us of his own precious and priceless mementos. His collection of magnets, instruments, charts, and manuscripts, the outcome of a life of ceaseless activity, he bequeathed to the Royal College of Physicians, who preserved it with all due care only to perish when their building was destroyed in the Great Fire of 1666. His house at Colchester still stands, his tomb in the church of Holy Trinity in that city still attests his virtues, and his memory is kept green at Cambridge by the Johnians, who claim him as one of the honoured worthies of their college. But his true monument, a monument "more enduring than brass," survives in the treatise which he bequeathed to mankind. It is this treatise which the newly-founded Gilbert Club proposes to reproduce, Englished in its phrase, but preserving with scrupulous fidelity all the peculiarities of the original, even down to the grain of the paper and style of the binding. The greatest electrician of the nineteenth century has been by common consent named President of the Club, and the rush for membership in it is a proof at once of the worthiness of the object and the fitness of the mode of action which has been chosen. The re-publication of "De Magnete" by English electricians is a fitting mode of commemorating the worth of this great Englishman.

SIR WILLIAM THOMSON'S CHAIN OF ELECTROSTATIC VOLTMETERS.

BY ANDREW W. MEIKLE, M.A.

(*Concluded from page 60.*)

The range of electrostatic measurement for ordinary practical purposes by the chain of instruments described above is complete from 25 to 50,000 volts; but, though little difficulty would be found in making an instrument, were it desired, to suit higher ranges, the problem of finding a convenient electrostatic instrument to give direct readings of potential below 50 volts is more difficult. No doubt a voltmeter of the Multicellular type could be made with a lower range, but in order to do so the length of the suspending wire, or the mass of the movable part, would require to be increased to such an extent as to render the instrument very cumbrous, and at the same time difficult to observe on account of the long period of vibration which its indicator would have. For laboratory and accurate scientific work a means of extending the range downwards is provided in the Quadrant Electrometer, which can be used when adjusted to best advantage to measure from $\frac{1}{100}$ to 40 or 50 volts. In the practical working of alternating installations it is seldom necessary to measure potentials so low as 50 volts, but for use with direct currents Sir William Thomson has invented a Magneto-static Voltmeter which gives direct readings from a small fraction of a volt up to 200 volts, and is found convenient for work with storage batteries and for other purposes. A description of this instrument will be given in a subsequent article.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"The Lighting of the Centennial International Exhibition, Melbourne, 1888 and 1889."*

BY K. L. MURRAY, C.E.

(Continued from page 69.)

The curves in the diagram (Fig. 3) were taken to ascertain the relative value of the magnetic circuits in the two classes of frames. The method adopted was as follows :—The commutator brush-holders were electrically disconnected from the field-magnet circuit. The ordinary brushes were taken out and replaced by others so bent that contact could be made with the commutator at the neutral point. The armature was run at the normal speed, and the field-magnets were separately excited by a variable current taken from an incandescent circuit. Simultaneous readings were taken of the current through the field coils, the potential difference at the terminals of the armature, and the speed of rotation. From these data curves were plotted as shown in the diagram. All the machines tested in this manner had similar thin-plate armatures. The resistance of the voltmeter used was great, so that the potential difference as shown by it was practically the electromotive force of the machine. As the number of windings and speed of rotation of the armatures were the same, the electromotive forces would be directly proportional to the total induction through the armatures. The induction through the armatures depends on the magnetising force (H) of the current in the field coils, and the goodness of the magnetic circuit. In the machines tested, the number of windings on the field coils were equal. Hence the electromotive forces of the different machines, when taken with the same current in the field, will

represent the relative values of their magnetic circuits. The curves may be taken either as saturation curves of the total magnetic circuit, or as curves of total induction through the armature, provided no sensible current is taken from it.

An examination of the curves in Fig. 3 will show a small magnetic advantage in favour of the solid frames. This result was expected, from the fact that the bed-plate increases the effective cross area of the field-magnet yokes, but is not likely to materially increase the magnetic leakage owing to the great length of circuit. The early part of curve of dynamo No. 460 was taken with the very greatest care. Only a few of the points are marked, for clearness, as the curve passed evenly through them all. The usual concavity at the commencement is shown in a marked degree. The slow rise of this curve for low degrees of excitation seems to indicate a greater degree of hardness of the iron. All the curves approximate to the same form over that portion of their length which corresponds with the ordinary range of excitation.

Table B shows the conditions of running and general behaviour of the machine shortly after starting. Very little more time was allowed before the measurements were taken than was necessary for the lamps to assume a proper working condition. At times, however, the tests had to be postponed till the machinery attained its normal speed. It will be seen that the current in most cases was above 10 amperes.

In Table C the more important values given in Tables A and B are compared, and their differences, with their proper signs, are added, to enable the alterations which take place when the machines and lamps are heated, to be more readily detected.

The current, in every case but one, fell as the evening advanced. This reduction is mainly due to the increase in resistance (due to heat) of the shunt circuit in the lamps. The effect of this is to lessen the action of the fine wire in the differential coils and allow the carbons to be separated a little farther ; that is, to increase the potential difference required at the terminals of the lamps. In ten out of twelve of the arc machines tested, the commercial efficiency was found to increase with the reduction of current that took place from the above cause. In the other two machines the current and efficiency rose or fell together. A comparatively small increase of current above the normal is found to produce a sensible diminution in the efficiency. Hence in practical work it is important to ascertain the most efficient current to take from the machines, and see that it is always maintained at that value. The increase in the efficiency may be partially due to a reduction in the losses caused by Foucault currents in the armature and field-magnets, brought about by an increase in the specific resistance of the metal by heat. The loss due to magnetic viscosity in the armature core may also be lessened by the same agency. It will be seen that the average output of the machines is much about the same whether they are hot or cold.

Current to Amperes Through Field Coils

FIG. 4.

The power absorbed by the machines is much less when they are hot—the total reduction in the twelve tested being 18 66, or 1·5 horse-power per machine, while the diminution in the output was little more than a quarter horse-power per machine. This fact accounts in some measure for the gradual increase in the speed of the engines (which has been previously mentioned) as the evening advanced, though the steam pressure and number of machines driven remained constant.

As there is no direct method of ascertaining the power absorbed by Foucault currents and magnetic viscosity while the machines are at work (the usual method being to find the value of all directly measureable quantities and subtract their sum from the total power absorbed by the machine, the balance being debited to the above causes), an attempt was made to find approximately the alteration in the magnitude of these losses corresponding with given variations in the total induction through the armature, by the following method :—The dynamometer pulley was placed on the machine to be tested, the field-magnets were arranged so that they could be separately excited by a variable current, and the commutator brushes were removed from the machine. The zero of the pulley was noted, and the machine then run at the normal speed, the deflection produced on the pulley indicating the power absorbed by mechanical friction. The field-magnets were then gradually excited and simultaneous deflections on the amperemeter and pulley

Machine cold.

noted, the speed of rotation of the armature being also taken. From the data thus obtained the curves on the diagram (Fig. 4) were drawn. It must not be forgotten that the value obtained for the waste power, corresponding with a given degree of field excitation, does not necessarily represent that which actually takes place when the machine is at work with the given degree of field excitation. The modifying influence of the current in the armature cannot well be estimated. The reduction produced by it in the total induction through the armature core would tend to lessen these losses. At the same time the losses in both armature core and pole-pieces would be increased, owing to the forward rotation of the field by the armature current crowding up, as it were, the lines of force into a smaller space, so increasing the electromotive force of the induced currents, the value of which is always $\frac{dn}{dt}$. Another source of difficulty in the Brush machine is the uncertainty of the effect produced by the great oscillation of the armature field (about 40deg.) owing to the small number of commutator segments. The curves shown in Fig. 4 present some striking peculiarities. The points from which the several curves start on the vertical line for C=0 may be regarded as their respective origins. The power indicated by the portion of the ordinates below this point is due to mechanical friction, and is constant for all degrees of excitation of the field. The curves Nos. 462A and B were taken with the machine cold and hot respectively. It will be observed that less power is wastefully absorbed when the machine is hot than when cold, and

Digitized by Google

that as the two curves start from the same point the difference is not due to mechanical causes. These curves show in the early part a very slow rise in the waste power for a given increment in the field excitation; but as the excitation is increased, the lost power rises with an increasing rate. On the same diagram the curves marked Nos. 1856A and B were taken with increasing and decreasing currents in the field coils respectively. By reference to table C it will be seen that dynamo No. 1856 is one of those in which the efficiency rises and falls with the current in the circuit. The curve taken with an increasing current is the only one of interest. The early portion is peculiar, and I can see no satisfactory explanation of the peculiarity. From the point where the exciting current is 4 amperes the curve is nearly a straight line, which, if produced downwards, would pass through the origin. In this machine, then, the power absorbed driving the armature (on open circuit) through the magnetic field increases directly as the current at least between the values C=4 and C=10. But the power required to overcome mechanical friction is constant. Hence, if the resistance of the circuit remains constant, as it practically does in this case, the efficiency of the machine will rise and fall with the current taken from it. Curve No. 460 was taken from the other machine, in which the efficiency and current rise and fall together. The power absorbed by the armature on open circuit increases at first very rapidly with the current; but when the current has reached 3 amperes the rate of increase is not so great, and it ultimately tends towards a small constant rate of increase.

P D At Terminals of Armature in Volts
No 462
No 460B
No 460 A
Current in Amperes Through Field Coils

Fig. 5.

Curves given in Fig. 4 express the horse-power absorbed in driving the armature (on open circuit) through the variable magnetic field as a function of the exciting current. This method of representation is purely arbitrary, though convenient when it is simply desired to ascertain the alteration in the power absorbed for a given change in the exciting current. The power required to drive the armature on open circuit through a magnetic field clearly will not depend on the value of the exciting current, but on the number of lines of force which the given excitation can force through the magnetic circuit of the machine. Those lines of force only which pass through the armature produce any useful effect. Consequently, if it is desired to ascertain the rate at which the lost power increases with the useful induction, the curves given in Fig. 4 should be expressed as a function of the total induction through the armature. The curves in Fig. 3 may be taken as curves of induction through the armature, expressed as a function of the exciting current.

The curve of induction through the armature of dynamo No. 460 is shown in the diagram (Fig. 5), and is marked No. 460A. The ordinates of curve No. 460B represent the power required to drive the armature (on open circuit) where the induction through it is proportional to the abscissa. A similar curve from dynamo No. 462, in which the power wasted is also expressed as a function of the induction through the armature, is added for the sake of comparison. The same peculiarities which have been already noticed are now shown in a more marked degree. Curve 460B tends towards a constant ratio between the waste power and induction through the armature. In dynamo No. 462 the waste power increases enormously, with high values of induction through the armature.

The distribution of energy supplied to three of the machines is tabulated on Table D.

The figures given in column 3 are taken from the ordinates corresponding to the given current in Fig. 4. They do not necessarily represent the true value of the loss when a current is taken from the armature. The figures given in the other columns are the result of direct measurements while the machines were actually at work. The data for the curves in Fig. 4 were taken before the machines were started on their respective circuits; they would therefore be comparatively cool. For this reason the distribution of the power absorbed by the machines when cold was selected, so that the values from Fig. 4 would be taken as nearly as possible under the same conditions. It will be seen that the difference between the measured total and the sum of the energy absorbed in the circuit and various parts of the machine is very considerable, especially so in the case of dynamo No. 460. In all three cases the power absorbed at the pulley is greater than that which can be accounted for. Probably this difference is due to an increase in the power absorbed by useless induction when a current is taken from the armature.

In Table E a few approximate data are given with reference to the general condition of the magnetic circuit of these machines. The values given were obtained with the armature running at the normal speed of 930 revolutions per minute on open circuit, the field-magnets being separately excited. In columns 9 and 10 respectively the total induction through the armatures, and corresponding values of B, are given. These and the dimensions constitute the only useful data. In columns 5 and 6 the corresponding values of B and μ for the field cores are given, assuming no leakage to exist. This, of course, is not the case. The figures simply indicate a low useful value of B in the field cores. When the machines are generating a current all the values given will be altered. The actual value of B for the armature of dynamo No. 460 would be 23,028 when the machine is giving a mean current of 10·1 amperes.*

The effect of the fluctuations in the current given by the machines was observed by carefully measuring the current given by the machine and the potential difference at the terminals of the field coils; immediately afterwards the resistance of the field coils was taken. The product of the measured resistance and current gives the potential difference requisite to maintain a steady current of the given value through the field coils. Subtracting this quantity from the potential difference actually measured, the remainder represents the mean E.M.F. due to self-induction.

Dynamo No. 460, hot.

(1) ..... Measured P.D. = 144·04 volts.
C = 11·09 amperes, R = 8·2 ω ∴ C R = 91·00 ,,

Difference ..... 53 ,,

(2) ..... Measured P.D. = 139·0 ,,
C = 9·82 amperes, R = 8·2 ω ∴ C R = 80·5 ,,

Difference ..... 58·5 ,,

Dynamo No. 460, cold.

(1) ..... Measured P.D. = 140·5 ,,
C = 11·33 amperes, R = 7·06 ω ∴ C R = 80·0 ,,

Difference ..... 60·5 ,,

(2) ..... Measured P.D. = 138·27 ,,
C = 10·85 amperes, R = 7·06 ω ∴ C R = 76·6 ,,

Difference ..... 61·67 ,,

From these data it appears that the current fluctuates about 1·5 per cent. on either side of the mean, or a total fluctuation of 3 per cent. If the current were steady the gain in the field coils only would enable the machine to feed one extra lamp with the same armature speed; but the efficiency of the machine would not be much affected.

Of the Victoria Brush dynamos (No. E2 used for incandescent lighting) only four (Table F) were tested to ascertain their commercial efficiency. Much more complete details of the behaviour of this class of machine are given in the various journals than can be found of the Brush arc dynamo. For this reason it was not considered worth while to multiply tests of the Victoria Brush machines. The method of testing was exactly similar to that used for the arc machines, excepting that both pistons in the dynamometer pulley were used, whereas in testing the arc machines only one piston was required.

* Armature E.M.F. = terminal P.D + C R + back E.M.F. in field coils.
= 1,220 + 126·25 + 57·2;
Total = 1,403·45 volts.

The very small current taken from dynamo No. 1,587 will account for the low efficiency shown, as the losses are almost independent of the output. As a whole, the efficiency of these machines is less than was expected.

To conclude. More complete tests, to ascertain the magnitude of the various losses which take place in the machines, the values of H, B, and μ, for both fields and armatures, the exact magnitude and form of the fluctuations in the current from the arc machines, and its effect in lessening the output from the machines, are much to be desired. It would also have been instructive to have made a long series of tests obtaining data from which curves similar to those given in Figs. 4 and 5 might be drawn, so ascertaining practically the law in accordance with which the power uselessly absorbed varies. The very considerable differences in the efficiency of the various dynamos, working as nearly as possible under the same external conditions, and having to all appearance similar armatures, is apparent, and the question is, To what are these differences due? It would seem that they must be caused by differences in construction, by which the deleterious reactions in the machines are altered; but if the tests which I have recorded in this Paper could have been extended, and made under various conditions, some light would probably have been thrown on the point. The close agreement of the curves in Fig. 3, and the great dissimilarity of those in Fig. 4, seem to indicate difference in the quality or arrangement of the iron forming the armature cores. There were no spare machines at the Exhibition, the whole number obtainable being in constant use; hence the tests made had to be confined to the shortest possible time, so that the lighting of the building should not be interfered with. This is the reason why further tests were not made, and also for the meagre and somewhat unsatisfactory nature of many of the data given.

TABLE F.—Victoria Dynamos, Hot.

No. of Machine.	Current in amperes.	P.D. at terminals, in volts.	EC / 746	H.P. absorbed at pulley.	Commercial efficiency.
					Per cent.
1823	192·96	108·49	26·06	36·28	77·34
1822	236·66	106·85	33·89	41·82	81·03
1587	90·013	97·66	11·78	17·71	66·52
1825	246·2	110·6	36·5	42·33	86·2

Such as it is, however, I submit this Paper to the members of the Institution of Electrical Engineers with the hope that there may be something in it which will draw forth remarks from some of them whose great experience makes anything they say valuable. At the Spencer-street Railway Station, Melbourne, I have had for some years a small installation of about 60 Brush arc lamps at work lighting the station yard, and I am now arranging for a central lighting station from which about 800 arc and 4,000 to 5,000 incandescent lamps will be lighted. Thirty of the Brush arc dynamos used at the Exhibition have been purchased and will be utilised, most of them being fitted with new armatures, which I will have made upon lines that I hope, and believe, will prove satisfactory. At any rate, I will avoid the evident errors in construction of the armatures sent out from England with these machines. If considered of sufficient interest, I will be glad at some future time to give the result of the work done, and also the details of some experiments made with a view to test the propriety of laminating the field-magnet cores as well as the armatures.

DISCUSSION (Authorised Abstract).

Mr. MORDEY said the author was to be congratulated on the great care with which the investigations described in the Paper had been carried out, particularly as no such tests had been previously made outside the manufactories. He thought, however, that Mr. Murray had given undue weight to the mechanical defects of the "thin-plate" Brush armature, for these defects were discovered at the Brush works before the opening of the Exhibition, and immediately remedied. Again, great stress was laid on the alleged fluctuations of the current from Brush dynamos. Some years ago, when Profs. Ayrton and Perry described their "Discontinuity" Meter before the Society, the speaker made tests on the currents in Brush arc circuits, but no discontinuity was perceived. More recently similar experiments have been made by passing the current through transformers, but no secondary E.M.F. could be detected. Referring to the effects of fluctuations, he could not see how the 3 per cent. variation was deduced from the numbers given, and as a possible explanation of the observed difference between the potential difference and the product C. R., the speaker pointed out that if a perfectly steady current passed through the armature, the Pacinotti projections would induce currents in the field coils. The comparatively low efficiencies of the Brush Victoria machines were probably owing to their being worked below their normal output.

Prof. AYRTON said he thought Mr. Mordey's inability to obtain evidence of discontinuity might arise from his using coils with iron cores and closed magnetic circuits, for in such apparatus very little effect is produced by small changes in the magnetising current. There was no doubt whatever that a great difference existed in the constancy of the currents from the Brush and Gramme machines used with the discontinuity metre.

Mr. MORDEY, in reply, said his 1882 tests were made with open-circuit transformers, and added that even if the supposed fluctuations did exist, they were of no very great disadvantage.

Mr. RAWORTH considered the efficiency tests gave results too variable to admit of much confidence being placed in them, for the many tests made at the Brush Works on various machines were so very regular that they had now ceased to make them. The method of taking the speed seemed open to serious objection, for the power may vary considerably during a minute. A well-calibrated tachometer would have been much more satisfactory. As regards breakdowns from defective insulation, his own experience in exhibition work proved that leaky roofs cause the majority of such accidents.

Replying to some remarks from Mr. Raworth, Prof. AYRTON said he had no desire to disparage Brush machines, and only wished to point out that the evidence of fluctuation obtained by the discontinuity meter received confirmation from Mr. Murray's results. He also added that the Paper under discussion contained internal evidence of imaginary accuracy, for to speak of ordinary commercial measuring instruments agreeing to one-hundredth per cent. was absurd: such instruments could not be read to the degree of accuracy implied by the statements made in the Paper.

Prof. S. P. THOMPSON thought arc and incandescent machines should not be judged from the same standpoint, for as the saturation of the iron is entirely different, the former could not be as efficient as the latter. Referring to fluctuation of current, he said that the two kinds of arc machines in common use (viz., Brush and Thomson-Houston), had both few parts in the commutator, and open-coil armatures. The E.M.F. of such machines must fluctuate considerably, but the large self-induction of arc circuits tends to steady the current. His own experience, however, proved that small Brush machines give fluctuating currents, but he thought the currents from large dynamos working long arc circuits would be steadier. As an instance of the necessity for large self-induction in such machines, a case was quoted where a Thomson-Houston machine refused to do its work when the fields were separately excited. In concluding, the speaker said the relative values of magnetic force and permeability were very disproportionate, and suspected they ought to be divided and multiplied by 10 respectively.

Mr. COUSENS said he had had considerable experience with arc plants in the Colonies, and had found the Brush machine very satisfactory. He had often noticed that the current decreased as the lighting continued, and that the lamps burn steadier as the time goes on. Cold weather also seemed favourable to steadiness. One of the chief mechanical defects he had experienced was the breaking of the commutator connections of shuttle-wound armatures, and when these were strengthened, the wires on the armature broke. Of the latter phenomena he was unable to give an explanation.

Mr. ESSON, speaking of the efficiencies, hot and cold, given in Table C, said he was quite prepared for differences of 2 or 3 per cent., but not for 10 per cent., as in some cases is there shown. The value of the Paper to electrical engineers would be considerably enhanced if the relation between the indicated horse-power of the engines and the useful electrical power had been given. His own experience with Phœnix dynamos driven from countershafting showed that with arc machines 66 per cent., and with incandescents 71 per cent., of the indicated horse-power was available at the terminals. These proportions can be increased by belting the dynamos direct to the engines. In conclusion, he protested against the idea that open-coil armatures were necessary for successful arc lighting, for ordinary Gramme armatures had been made to give 1,500 volts satisfactorily.

Mr. KAPP considered the table of efficiencies very interesting, and thought they deserved careful study. From table A the efficiencies of "thin-plate" armatures were decidedly greater than those with thick plates, thus showing the advantages of lamination. The objection to the use of thin plates, viz., expense, weakness, and space wasted by insulation, were not insuperable, for the additional expense was not prohibitive, and he was glad to hear from Mr. Mordey that the defects of weakness had been satisfactorily overcome. As regards waste space, by insulation, he said that this need not exceed 8 per cent., and that some makers had ceased to use any insulation between the plates. Speaking of the fluctuation of current, he thought all agreed that the E.M.F. of Brush machines fluctuates, and the effect of self-induction was to reduce (not to destroy) the variations in the current.

Mr. ADDENBROOKE, who happened to be in Melbourne at the close of the Exhibition, gave an account of the general appearance of the installation, which he characterised as very neat. From what he heard, the lighting was considered very satisfactory, the arrangement in the picture galleries being particularly good. He was also informed that the transformer plants supplied by Messrs Ganz and Co. and the Thomson-Houston Company worked well. The boilers used were of a combined locomotive and marine type, with tubes and return flue, and the engines seemed to be an exact copy of Marshall's two-cylinder high-pressure type.

Mr. PREECE said Mr. Murray had entrusted him with the care of the Paper, and he was sure its reception would be very gratifying to the author. He himself would have liked more information about the behaviour of the arcs and the amount of illumination employed. Speaking of his own experience in Exhibition lighting, he remarked that in determining the power necessary, he totally disregarded the nominal candle-power of the lamps, and based his estimate on the number of watts per square foot of floor space. As a matter of experience, he found half a watt per square foot gives brilliant illumination, and one-third of a watt was enough for most purposes.

Dr. HOPKINSON (who was in the chair), in confirmation of Mr. Mordey's and Mr. Raworth's statements, said that his tests showed the Victoria dynamo to be very satisfactory, the efficiency being 92 per cent.

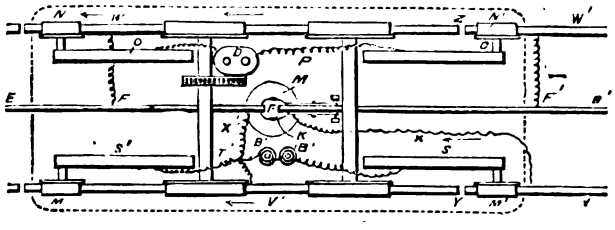
THE WHELESS ELECTRIC RAILWAY SYSTEM.*

An electric railway system has recently been devised by Mr. Malone Wheless, of Washington, D.C., by which the use of a conduit has been avoided, the conductor being placed below the surface of the street. Experiments are now being carried on in a practical way, which, it is hoped, will demonstrate the success of the plan.

The accompanying illustration shows diagrammatically the system employed, though in practice some of the details have been changed. The conductor *E E'* is laid in a conduit between the tracks and is completely covered, leaving no opening between the rails. Extending from the conduit line, at *f f'*, are wires which are attached to separate rails on one side of the track. By the use of these wires the current can be circuited through the motor and then be led back to the conduit line. The armature *K* of the magnet *M* serves to keep the conduit line closed at *r* by resting against the two ends of the line when the magnet *M* is "dead;" but when the magnet *M* is energised the conduit line is opened by the withdrawal of the armature *K*, and the current seeks the rail *W* through the wire *f*. It then flows in the direction of the arrow into the small wheel *n*, which is supported on a metal arm *o*, and is from there carried to the motor *D*, thence along the line *p* to the metal arm *o'*, and passes down this arm through the small wheel *n'* to the rail *W'*. When the current reaches this rail it must pass back to the conduit line through the wire *f'*, as the opening at *z* gives it no other route. In other words, it will be noticed that the current is simply circuited through the motor on the car by the fact of opening the conduit line at *r*. The supporting wheels of he cart perform no part in the circuiting of the current through the car, as they are made non-conducting by being provided with papier maché centres, and the current flows through the motor from one of the small wheels to the other.



Plan of the Connections of the Wheless Car.

The magnet, which serves to open the conduit line by withdrawing the armature, is energised from a storage or other battery placed upon the car. The two small wheels *m m'* are supported by metal arms similar to those shown at *n n'*, and occupy a distance on the car greater than the length of the rail. In this manner one wheel is always on one rail and one wheel on the next rail. It will be noticed that the wires from the magnet in the conduit are fastened in like manner, *i.e.*, one wire to one rail and the other wire to the next rail. In this way the contact of the small wheels *m m'* with the two rails serves to close the circuit in the conduit magnet as the car moves. The manner in which this is effected is as follows: *B' B''* are cells of the battery carried on the car. From *B''* one wire is led to the metal arm *S*, and thence to the rail *V*, through the small wheel *m'*. Now the rail *V* is insulated from the rail *V'* by the opening at *y*. Therefore, the current traverses the line *x* in the direction of the arrow, passes around the magnet *M*, thence to the wire *x'*. From *x'* it travels to the rail *V'*, pursuing the direction of the arrow to the small wheel *m*, and from there to the metallic arm *S'*; thence along the wire *t'* to the other pole of the battery at *B'*, and the magnet *M* is energised. The result of this, as already shown, is to open the conduit line and throw the circuit around through the motor on the car. This operation is repeated as the car passes over every rail, and a uniform speed is acquired.

* From the *Electrical World*.

The Brazilian Government and the Western and Brazilian Telegraph Company.—It will be interesting to note the attitude of the new Brazilian Government towards this Company in the matter of the dispute with the Director-General of the State Telegraphs over the loop cable which the Company is prevented from laying. Rio advices of October 28th state that the late Minister of Agriculture had contemplated placing a "fiscal" in the offices of the Company. Such a proposal was regarded in Rio as a gross abuse of privilege.

LONDON CHAMBER OF COMMERCE.

The Electrical Trades' Section and the Edinburgh Exhibition.

The following reply to the report of the Special Committee (*The Electrician*, November 15th, p. 33) was received from Mr. Lee Bapty at the meeting of the Section on Monday last:—

To Major S. Flood Page, the Electrical and Allied Trades Section of the London Chamber of Commerce.

SIR: I have placed before my Council the report of your Special Committee on the Edinburgh Exhibition, and am instructed to communicate the decision at which they have arrived as under. The concessions offered are such as have never before been granted, and will, I trust, be found of such a nature that you will be able to recommend them for acceptance by your Section. I need not further enter into the matter of your Section, not having been consulted by my Council before issuing their Prospectus, but would repeat that there was no intentional neglect nor discourtesy meant. The first point of importance is contained in

Paragraph 5.—WITH REGARD TO PAYMENT FOR SPACE, my Council have approved the suggestion I made when attending your Committee on Monday week last, and will undertake to return to exhibitors of electrical inventions, apparatus, plant, &c., all moneys which they may pay to the Council by way of rent for space, provided the net surplus be sufficiently large to enable them to do so, and in the event of a smaller surplus to refund a *pro ratâ* amount. I may say that a surplus is practically certain.

Paragraph 6.—MOTIVE POWER.—My Council are prepared to concede to your wishes with regard to steam or belt-power, which will be supplied free, and with regard to electric current, the power necessary to generate it will be given, but the dynamos should be provided by some of your exhibiting firms.

Paragraph 7.—ATTENDANTS.—I note the suggestion of your Sub-Committee, which is very practical, and I shall be glad to assist in any way I can to reduce exhibitors' expenses in this direction, by allowing the ordinary Exhibition attendants to help your technical attendants when extra manual labour is required.

Paragraph 8.—INSURANCE.—This is a matter which my Council cannot see their way to undertake. Bnt I am instructed to say that every possible precaution will be taken to *prevent* a fire; the most efficient apparatus will be provided, stringent regulations will be carried out, an efficient force of firemen and watchmen will be on duty night and day, and the whole staff will be regularly drilled in fire exercises. I may add that at the Royal Jubilee Exhibition, Manchester, where we had about four millions of pounds' worth of property, not one claim was made, and this I attribute entirely to efficient watching and proper apparatus, and I intend to introduce exactly the same system here, so that the risk of fire will be reduced to a minimum.

Paragraph 9.—AWARDS.—My Council are prepared to practically abide by your suggestion as to awards and the choice of judges, and, in case it should be decided to institute practical tests, will provide the necessary power; but the other costs incidental they think should be borne *pro ratâ* by the exhibitors competing.

Paragraph 10.—TESTING, &c.—My Council concurs entirely in your views, as expressed in this paragraph.

Paragraph 12.—I sincerely trust that, as your wishes have been so fully if not entirely met, the entire trade will now co-operate with us as foreshadowed in the paragraph, and, with your aid, we shall have the finest Electrical Exhibition ever held.

In reference to the request of an extension of time for the entries, which is not mentioned in your Sub-Committee's report, I will bring the matter before the Executive Council, who will have much pleasure in acceding to your request, only urging that, although the closing date will be altered to January 1, 1890, the applications will be sent in *as soon as possible* to facilitate arrangements. The lighting will, of course, be provided by contracts, for which specifications will be at once issued.

I think I have now fairly covered the ground of your Committee's report, and again reiterating the hope that we may now reckon upon your cordial co-operation,

S. LEE BAPTY, General Manager.

After hearing Mr. Lee Bapty's reply, the Committee passed the following resolution unanimously:—

"*That Mr. Lee Bapty's letter be circulated, together with copy of the report of the Special Committee, to each member of the Electrical Section, and each member be requested, not later than December 5th, to inform the Secretary of the London Chamber of Commerce, Eastcheap, E.C., for the information of the Committee, whether he, or his firm, or Company, purpose exhibiting at Edinburgh on these terms.*"

The proceedings then terminated.

THE PHYSICAL SOCIETY.

At the meeting of this Society on the 15th inst. Mr. H. TOMLINSON read a Paper on

"The Effect of Repeated Heating and Cooling on the Electrical Resistance of Iron."

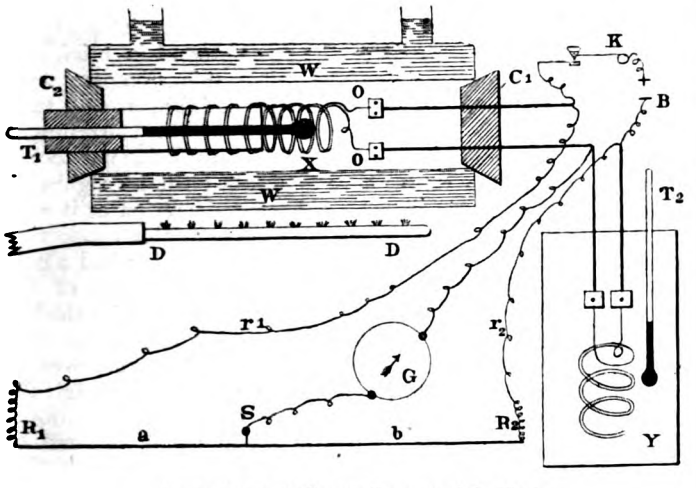
The author began by pointing out that some of the physical properties of iron wire, even after annealing, are known to be capable of considerable modification by repeated heating to 100deg. followed by gradual cooling. For example, the internal friction of a torsionally oscillating iron wire can be permanently reduced to a considerable extent in this manner, and in a Paper recently communicated to the Royal Society the author showed that both the molecular friction and the magnetic permeability of an iron wire could be reduced in this way to one quarter, and less than one-half, respectively, of their original values. There was at the same time a considerable diminution in the temporary temperature effects on both properties.

The object of the investigation described in the present Paper was to determine whether the electrical resistance and the temperature coefficient of iron underwent a similar change as the result of alternate heating and cooling.

According to Matthiessen's formula

$$R_t = R_0 (1 + a\,t + b\,t^2).$$

where R_0 and R_t are the resistances of a metal, and a and b are constants. For most pure metals a does not differ much from ·00366, and therefore the resistance is approximately proportional to the absolute temperature. In the case of pure iron, however, the value of a is much larger, and the author thought that it might, by alternate heating and cooling, possibly be reduced to some value not differing much from ·00366. This, however, was not found to be the case.



Apparatus and Connections used in Tests.

The iron wire was annealed by heating it to a temperature of about 1,000deg. in a tube inserted in a Fletcher tube furnace, and the temperature was maintained at this point for some hours, after which the wire was allowed to cool slowly, without removal from the furnace. This process was repeated on three different days. In order to minimise the effects of the earth's magnetism, the tube was fixed in the furnace in a position at right angles to the magnetic meridian. The wire was about three metres in length and one millimetre in diameter, and, after annealing, it was wrapped round with paper doubled on itself, and then wound into a coil five centimetres in diameter and twelve centimetres in length. It was then introduced into an air-chamber formed of two co-axial copper cylinders connected at their extremities, and enclosing between them an annular space filled with water.

The arrangement of the apparatus is shown in the diagram above.

O O are two clamps, grooved to receive the ends of the iron wire X, and soldered to stout copper connecting rods. A German silver wire, Y, is similarly connected, and enclosed in a glass vessel; $a\ b$ is a platinum-iridium wire, having a resistance of ·1 ohm; R_2 is a resistance of 100 ohms; R_1 a set of resistances from ·1 to 200 ohms; r_1, r_2, indiarubber-covered connecting pieces, each having a resistance of ·05 ohm at the temperature 17deg.; and S is a sliding piece, making contact with any point of $a\ b$, on pressing a button. At the ordinary temperature of the place of observation the resistance of Y was very nearly equal to that of X, and R_1 was nearly 100 ohms; and, therefore, any slight changes in the temperatures of r_1, r_2, and $a\ b$ would not sensibly affect the balance. The temperatures of X and Y were registered by the thermometers T_1 and T_2. The former had its bulb in the centre of the coil X, and was enclosed in the glass tube M, having its end outside the air-chamber lined with indiarubber, so as to allow of the thermometer being pulled out for reading. The thermometer T_1 and the glass tube were both slightly inclined upwards to prevent the mercury column from breaking when the temperature was falling. To maintain a constant temperature inside the air-chamber, the ends of the latter were closed by corks, C_1C_2, and the vacant spaces inside were stuffed with cotton-wool. The water in the annular space W was heated by a row of gas-burners, DD, by means of which it could be maintained constantly at 100deg. for many hours, and very approximately constant for some hours at a lower temperature. G is a galvanometer, B a battery, K a key. As shown in the diagram, the ratio X : Y was determined by means of a Wheatstone bridge arrangement. Instead of closing the battery circuit first and the galvanometer circuit afterwards, as usual in Wheatstone bridge measurements, in order to get rid of the kick due to self-induction, the author preferred to keep the galvanometer circuit constantly closed, which enabled him to get rid of some troublesome thermo-electric effects, and the self-inductive effect was eliminated by extending the observation over two or three seconds.

The bending of the iron wire into the form of a coil, as was to be expected, increased its resistance slightly—about ·25 per cent.—and a small portion of the observed effect was doubtless due to the gradual dying away of this increase. In making the observations the wire was left undisturbed for several hours, and its resistance and temperature determined, after which the temperature was raised to 100deg. as nearly as possible, and maintained at that temperature for at least eight hours, during which period the resistance was measured several times. The wire was then allowed to cool, and its resistance again determined about 16 hours afterwards. These operations were repeated until no sensible change of resistance was produced by the heating and cooling.

The results are given in the following table:—

Number of times heated to 100° C.	Specific resistance in C.-G.-S. units at 17° C. R_{17}.	Differences between consecutive values of R_{17}.	Specific resistance at 100° C. R_{100}.	$R_{100} - R_{17}$.	$\frac{R_{100} - R_{17}}{R_{17}}$.
0	11162	.....	.....	.....	.....
1	10942	220	16029	4952	·4527*
2	10807	135	15796	4922	·4526*
3	10772	35	15789	4985	·4613*
4	10757	15	15747	4999	·4633*
5	10755	2	.....	4996	·4638*
6	10727	28	15724	.....	..... †
7	10711	16	15679	4983	·4629‡
8	10694	17	15674	4965	·4636‡
9	10689	5	.....	.....	..... ‡
10	.....	.....	15654	.....	..... ‡
11	.....	.....	.....	.....	..... ‡
12	10688	.....	.....	.....	..... ‡

* Kept at 100deg. for eight hours; battery current always applied in the same direction.

† Kept at 100deg. for 26 hours; the battery current applied first in one direction and then in the opposite.

‡ Kept at 100deg. for eight hours; the battery current applied first in one direction and then in the opposite.

It will be seen from the table that the specific resistance both at 17deg. and 100deg. was diminished at each repetition of the heating and cooling process until finally it attained a value about 4·5 per cent. less than its original one, so that although the permanent effect on the electrical resistance is much less than on the permeability, for very minute magnetising forces, it is yet quite sensible.

At the sixth heating the temperature of 100deg. was maintained for twenty-six hours, and the direction of the current was frequently reversed, a proceeding which was found to increase the rate of diminution of resistance.

The sixth column of the table shows that the temporary temperature effect on the resistance is not diminished by the alternate heating and cooling, but the temporary increase of resistance per unit becomes greater in proportion as the specific resistance itself diminished. The formula deduced by the author from his observations is

$$R_t = R_0 (1 + ·005131\,t + ·0000315\,t^2);$$

whilst that deduced from Matthiessen's results for pure iron annealed in hydrogen was

$$R_t = R_0 (1 + ·005425\,t + ·0000083\,t^2).$$

Digitized by Google

The author, in conclusion, expressed the hope that the British Association Committee on Electrical Standards might be induced to determine the absolute resistances and the temparature coefficients of the pure metals in general use.

DISCUSSION.

In the discussion which followed the reading of the Paper,

Dr. WALMSLEY inquired what were the magnetic forces for which the permeability of the iron wire was determined? In reply to this the author stated that the magnetising forces were so extremely minute that the permeability might be regarded as sensibly constant.

Prof. PERRY did not consider this assumption justifiable, as the magnetising curve differs considerably from a straight line for small magnetising forces.

Prof. AYRTON thought the author was justified in his assumption, for even if there were a loop in the curve, the points on it would practically be in a straight line if the loop were extremely small, as would probably be the case when the magnetising forces were confined within such narrow limits.

THE LONDON COUNTY COUNCIL AND OVERHEAD WIRES.

The following are some of the powers which the London County Council propose to obtain under their London Subways and Overhead Wires Bill, to which we referred in our issue of October 25th :—

To provide for the removal of all wires in the county of London which are placed overhead, or such of them as the Council may require to have moved, and to require the owners thereof to remove the same, either underground or into the subways, or to such other position as the Council may determine, on such terms and conditions as may be prescribed by the Bill, and to prohibit the placing or maintenance of any tubes, wires, or other appliances over, above, along, or across any street, or within such distance thereof as may be defined in the Bill, except with the consent of the Council, and subject to and in accordance with such terms and conditions as the Council may impose, or as may be defined in the intended Act.

To provide for the registration, inspection, and regulation of such existing overhead wires as may not be removed, and of any wires hereafter permitted to be placed overhead, and to enable the Council to make and enforce bye-laws and regulations, and to require the alteration and strengthening or renewal of overhead wires or supports of overhead wires, and generally to prescribe the materials and method to be employed in placing, insulating, protecting, and supporting such overhead wires.

To enable the Council to remove disused wires, and to require owners of wires to renew, alter, or repair their wires, standards, and supports.

To empower the Council in certain cases to authorise the attachment of overhead wires to houses or buildings, and to provide for determining and assessing what compensation shall be paid to the owners or occupiers of the houses or buildings in respect thereof.

To confer powers upon the owners or occupiers of houses or buildings over or to which wires have been placed or attached, to require the removal or alteration thereof at the cost of the owner of such wires, and in default to provide for the removal thereof, and to impose penalties for breach of any of the provisions of the intended Act, or any bye-laws or regulations to be made thereunder.

To authorise the Council to appoint and employ inspectors for any of the purposes of the intended Act, and to charge and recover fees in respect of work performed by them, and in respect of the registration of wires.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 16, 1889.

The Postmaster-General and the Western Union Company.—There appears to be serious trouble growing between the Government and the Western Union Telegraph Company. In my last letter to you I mentioned that Mr. Wanamaker had reconsidered the scale which he attempted to put into force a few months ago for Government messages, and had established a new rate, averaging about a cent. a word, which he thought might be acceptable to the Company. In advising the Western Union Company of this change in the schedule, Mr. Wanamaker threw out the suggestion that it would be well to have a commission to inquire into the subject, to find out what the service was honestly worth, and to fix rates accordingly. It was supposed that possibly the Western Union Company might accept these new terms without much ado, even if they were still unjust; but it now appears that the great Corporation has no intention of accepting Government work at the rates fixed, without a very strong protest. In fact, it begins to look as though there might be a resort to the Courts if the rates are insisted upon. Dr. Green says that if the entire message business of the Company for the fiscal year just closed had been sent at the rates last named, the total receipts would have been about $4,000,000 less than the actual cost of transacting that work. Taking the Government messages to average 15 cents. each, the total returns of the Company would show the deficit named; while even if the Government messages were much longer than is thus estimated, and should yield an average of 20 cents. each, there would still be a deficit of $2,000,000 on the message business of the Western Union Company. It is hardly to be expected, therefore, that Dr. Green, of the Executive Committee of the Company, should agree to accept the revised schedule. Dr. Green says that the Post Office Department has no right to seize upon rates which the Western Union Company has had to resort to when fighting competition, and use those rates as a basis for charges to the Government. Dr. Green says that the Company has been done injustice before of this kind; but it was ascribed to erroneous judgment. Upon the present occasion, he remarked, however, "A course is pursued which gives your high official sanction to an attitude towards us which we consider so unjust and so well calculated to operate prejudicially to our general telegraph business, that we feel compelled to enter our earnest protest against it." The Company is highly favourable to a Board of Arbitration, and professes itself ready to supply the fullest information as to the cost of telegraphic business. The resolutions adopted by the Executive Committee of the Western Union Company cover the same ground in brief, and wind up as follows:—"Resolved, that this Company will transmit, as heretofore, with due priority and diligence all telegraphs between the several departments of the Government and their officers and agents; but this Company will not accept as final payment the rates above established till its rights in that regard have received such further consideration as it may be able to secure." It is interesting to note in this connection that a few days ago Postmaster-General Wanamaker had a conference in Washington with the postmasters of some of the largest cities in the Union. It is understood that the subject of postal telegraphs was brought up, and that Mr. Wanamaker sought to ascertain how far these officials would be able to carry out his scheme for the delivery of cheap telegrams through the Post Office. There is a general belief that at the opening of Congress next month the subject of postal telegraphs will be brought up, and that Mr. Wanamaker will urge it in his report as strongly as possible.

The Massachusetts Electric Lighting Association.—An interesting new departure in electric light organisation was taken last week in the formation of the Massachusetts Electric Lighting Association. A call having been issued for the purpose, a meeting of representatives of central station companies was held in Boston, when about forty companies, of a total capitalisation of about a million pounds, participated, all the different systems being included. The membership of the new association is limited to general station companies doing an electric light and power business for commercial purposes, and does not exclude gas companies which have electrical interests. The new association settled down to business at once, adopted its by-laws, elected its officers, and is already in good shape to look after the interests of the corporations with which its members are connected. There seems little reason to doubt that this is the first public sign of a movement which is likely to become general, and which will result in the formation of State Associations all over the country. It is, of course, too much to expect that an association will be formed in every State, because in some parts of the Union the material is still somewhat scanty; but we shall probably see several strong State organisations at an early day, and these will be able to do a great deal of good in safe-guarding interests which have often been peculiarly liable to the attack of those who make municipal and State legislation a cover for

Digitized by Google

various forms of exaction. These Associations will in nowise conflict with the work of the National Electric Light Association, but will strengthen that body, and will probably in some way form a part of its membership. It is early yet, I suppose, for the organisers to outline their programme, but I should not be surprised to see the National Electric Light Association in a short time settle down to one meeting a year, while the various State Associations will hold their meetings *ad interim*. In this way activity and vigilance will be continuously maintained, and electric lighting interests throughout the country will be vastly improved.

Senators and Overhead Wires.—During the last week or two the newspapers have, as a general thing, discontinued their wild talk about the dangers of electricity. It is too much, however, to expect that the companies will be let alone for a very long time, and thus we find one of the morning papers canvassing the New York State Legislature to ascertain how the Senators and Assemblymen propose to act in regard to the subject. This paper has asked each of the representatives, first, whether they would favour legislation for controlling the electric currents along our streets within the limit of safety; and next, whether they will join in a conference, irrespective of party, for the purpose of drafting a bill to enforce such control. It is needless to say that a great many of the gentlemen have availed themselves of the opportunity for playing to the gallery. One of them replies, "Count on me to labour for the protection of our workmen and defenceless women and children against the deadly wires." Another one replies very naïvely, "The wires should be put where they will be safest: Edison says the subways will not be perfectly safe, but in this matter I shall be guided by what experts say." One really sympathises with Mr. Edison thus to find him excluded from the noble army of experts. Another Masaniello says, "Too many lives have been sacrificed to the grasping greed of monopoly, and it is high time to put a stop to these outrages." But I refrain, though I could add a number of other responses not less amusing and laughable.

Electric Traction at Boston.—The manner in which the West End Electric Railway Company in Boston is getting ready to equip its whole system with electricity is an earnest of its thorough belief in the advantages of the system, and the desirability of making the change from horses as quickly as possible. Work has been carried on all over the city in connection with the equipment of the circuits, and the central power station is rapidly assuming a business-like appearance. It will contain Thomson-Houston generators, to be driven by thirteen engines, each of 1,000 horse-power, of the Reynolds-Corliss type, and guaranteed to work on 13lb. of water per horse-power per hour. Another interesting feature of this preparation work is the educational process that is going on. Last week, for example, a large number of the *employés* of the Company, together with the various superintendents, were brought together and given a practical lecture by Mr. George W. Mansfield as to the nature and special requirements of the new class of work. There can be no doubt that this lecture will do good, and will give the men useful ideas as to the machinery with which they will have to deal, and the best manner of running it efficiently and economically.

The Patent Laws.—The great increase in the number of electrical patents tends more and more to bring home to the electrical inventor some of the serious defects of our patent system, which, while a good one on the whole, is susceptible of material improvement. It very often, and indeed generally happens, that the prolific inventor is a poor man. At the present time, if he has an invention which he wishes to protect and yet to have time to develop, his only course is to obtain a caveat. This method is, in a measure, costly; and of course, where the inventor's funds are limited, is virtually out of the question. It is now proposed by an inventor, in one of the electrical journals, that instead of the caveat system there should be adopted by the Government a system of safe deposit vaults where the inventor could place under lock and key with the supervision of the Government a complete description and illustration of his invention or process. In this way any number of inventions could be placed on deposit, and, it is argued, all the money and time squandered in disputing and establishing priority would be saved. The proposer of this scheme contends that on account of the greatly increased and complicated matter before the Patent Office, some plan of this kind will soon be a necessity. It is no doubt a fact that the present system of interferences and determinations of priority is open to serious objection, and every new development in electricity only goes to show how great its burdens are. The present conflict over alternating current motors, and the one now arising over the conversion of the alternating into continuous currents, are two examples of the difficulties in the way of satisfactorily determining priority as things are now.

PARIS NOTES.

(FROM OUR CORRESPONDENT.)

November 23, 1889.

The Municipal Station at the Halles, which is to be inaugurated on Sunday next, is due, it will be remembered, to the decree of the Conseil Municipal of July 27, 1888. The 18 months which have elapsed since this preliminary step was taken, have not been wasted, though, perhaps, the work would have got on faster had there been less bickering on the subject of the employment of foreign electrical material. The station is entirely underground. The steam plant comprises 6 Belleville boilers, working at 140lb. pressure, 3 100-kilowatt triple-expansion Weyher and Richemond engines, and 3 125-kilowatt Lecouteux and Garnier engines. The electrical plant consists of 6 110-volt 450-ampere Edison dynamos, running at 600 revolutions, and driven in pairs by the Weyher and Richemond engines, and of 3 Ferranti alternators, running at 500 revolutions, and giving 2,400 volts and 50 amperes. The Ferranti machines are cord-driven by the Lecouteux and Garnier engines, belt gearing being employed in the case of the Edison dynamos. The current for the lighting of the Halles and of the houses in the vicinity will be supplied on the three-wire system by the Edison machines, each pair of dynamos being coupled in series, and all three groups being arranged in parallel. The Ferranti plant is intended for long-distance lighting. The basement of the Halles are lighted by 450 incandescents, while 170 arc lamps, arranged four in series across the mains, are used above ground. The cables, which have been supplied by the Indiarubber, Gutta-percha, and Telegraph Works Company from their factory at Persan-Beaumont, are run under the pavements in cement troughs, the conductors being supported at intervals by enamelled iron hooks screwed into wooden cross-pieces. The authorities propose to supply current by meter at the rate of 15 centimes per 100 watt-hours with a reduction for a larger consumption. The total cost of this station will certainly not be less than £40,000, and no pains have been spared to make it both an engineering and financial success.

The Conseil Municipal have just purchased the Edison Central Station at the Exhibition, and intend to make use of it in connection with the luminous fountains which are to form a feature of the park which is to take the place of the Exhibition buildings. I understand that the capacity of the plant will be increased and the area of supply extended. I may mention in this connection that it is reported that the electric lighting of the Boulevards will probably be continued until March, 1891.

A company, called the Compagnie Nationale d'Electricité, has recently been registered, with a capital of £200,000, to work the Ferranti system in France.

CORRESPONDENCE.

SINGLE-MAGNET DYNAMOS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the letter of Messrs. Willans and Robinson in your issue of the 8th inst., may I point out that the unequal magnetic pull on the armature in dynamos of the single-magnet class is largely due to the questionable practice of reducing the cross-section of the limbs at the crown of the poles. It has been said that since through *a*, Fig. 1, the magnet has to carry only half the induction, there is no necessity for the cross-section of this part to be greater than half that of the limb at *b*; but when it is remembered that absolute symmetry of the field could only be obtained if the path *e f* were of similar resistance to the path *c d*, the desirability of keeping up the cross-section so as to secure the diminished

Digitized by Google

resistance of a feebly-saturated pole-piece becomes at once apparent. To illustrate these remarks, Fig. 2 may be cited as representing a design in which this point has been kept in view, while from the same standpoint Fig. 1 is a magnetic absurdity.

The magnetic pull may be neutralised by placing the armature eccentrically in the polar cavity, as suggested in a letter of mine published in *The Electrician* of December 9, 1887. The mere closing in of the limbs after boring, to make the air-gap increase both ways from the crown of the poles to the tips, though mitigating the evil to some extent, does not give such satisfactory results as displacing the armature centre.

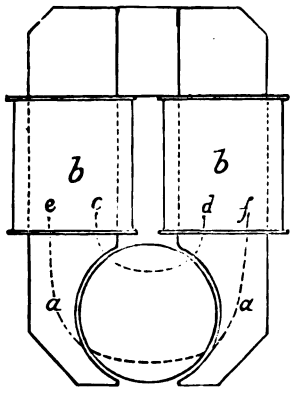


FIG. 1.

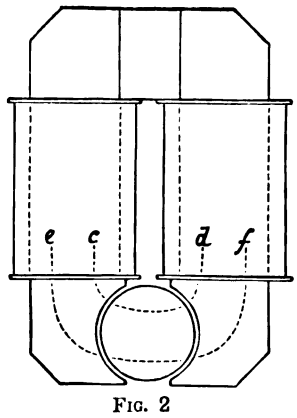

FIG. 2

A new departure in the construction of single-magnet machines with ring-wound armatures has been recently made by my firm. A cross-section of the field is shown in Fig. 3, the magnet limbs and part of the poles being of *wrought* iron, while the top tips, *p*, which are fastened on separately, are of *cast* iron. The object, of course, is to interpose in the path of the induction *c d* through the top half of the armature such resistance as will compensate for its diminished length as compared with the path *e f*.

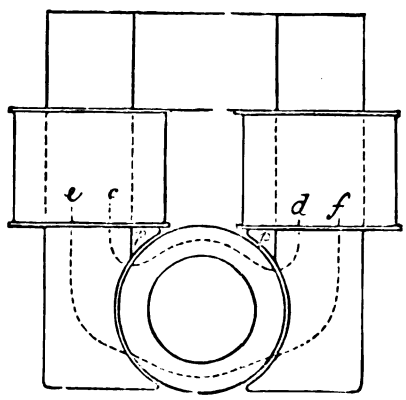

FIG. 3.

This device, which is applicable to drum as well as ring armatures, may be further modified by introducing a gun-metal liner in the joint between the wrought and cast iron, or by altering as may be necessary the shape of the castings.—Yours, &c.,

W. B. ESSON.

London, November 20, 1889.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Having listened for two weeks to the plaintive wail of "Telegraphy" to the effect that no representatives of submarine telegraphy were invited as guests to the dinner of the professional body to which all real submarine telegraph engineers already belong, I beg to offer in your columns a still more bitter cry. Not a single invitation was addressed by the Council to any representative of electric lighting interests, nor to any representatives of the telephonic interests, nor to any representatives of the electric motor interests, nor even to any of the professors at the electrical colleges. Why did the Council perpetrate the extraordinary oversight of not inviting any of these? Strongly as I deprecate the formation of a new Society, the inquiry naturally suggests itself whether an Institution which neglects to invite representatives of three main branches of electrical engineering, and of the budding electrical engineers, can be considered fairly representative. Such a lack of catholicity demands both explanation and apology.—Yours, &c.,

ELECTRIC LIGHT.

LEGAL INTELLIGENCE.

In the Halifax County Court recently, before Judge Cadman, the case of Blackburn v. Smith and Co. was heard. It was an action in which Mr. R. S. Blackburn, electrician, carrying on business at Hebden Bridge, was plaintiff, and Messrs. Frederick Smith and Co., wire drawers, Halifax, were the defendants.

Mr. SHAW, for the plaintiff, said that in the month of April last the plaintiff undertook a contract to construct a line of telegraph at Newhey, near Rochdale. He ordered from the defendants, by letter, one mile of copper telegraph wire, which he instructed them to forward "per luggage" to his address at Newhey. This wire was ordered on April 14th, and was sent off from Halifax on the 24th, and ought thus to have reached Newhey on the following morning. But, in consequence of being miscarried by the Lancashire and Yorkshire Railway Company, the wire did not reach its destination until April 27th (Saturday). By reason of this delay, three men employed there by the plaintiff were kept waiting for the wire. The plaintiff himself lost one day, and also expended certain moneys in travelling in search of the goods. For this loss he sought to claim the sum of £2. 10s. 1d. The plaintiff preferred a claim against the Railway Company for the loss sustained, but the Company declined responsibility on the ground that the wire had been sent by the defendants not according to the ordinary conditions, but subject to the special conditions attaching to the consignment of goods at owner's risk, which conditions relieved the Railway Company from liability "except upon proof of wilful misconduct on the part of the Railway Company's servants." The defendants also refusing to pay, were sued for the loss sustained by the plaintiff, inasmuch as they without his instructions or even knowledge, negligently did consign the wire subject to the conditions as to owner's risk before referred to, and it was not incumbent upon him (the plaintiff) to bring an action against the Company and give proof of such wilful misconduct. Evidence was given by the plaintiff that it was not customary in the trade without special instructions to consign copper telegraph wire at such a perilous risk.

It was contended by the defendants that they were not liable, on the ground that they had consigned the wire according to their usual practice, and that the plaintiff having paid the carriage he was the owner of the wire, and cases were cited in support of this.

HIS HONOUR held that in this case the time occupied in the transit of goods over a distance of about 20 miles was such that the Railway Company were guilty, through their servants, of wilful misconduct, and they were the party thus liable on that account. After further argument, his Honour decided that the defendants having been instructed to forward the goods "per luggage," were justified in forwarding the same at owner's risk, and especially as by so doing they had saved the plaintiff the full rate of carriage otherwise payable. He suggested that the plaintiff should bring an action against the railway company, whom he considered were guilty of wilful misconduct in the matter. He was therefore obliged to enter a nonsuit for the plaintiff.

THE KENT ARC LAMP.

The brake action of the Kent unifocal arc lamp, which is noticeable for the simplicity of its working parts, its lightness and shortness—its entire length being only 2ft. 2in.—is shown in Fig. 1. W is a wheel with three flat-bottomed recesses turned in it, two being for the feed-chains and one for the "break-band." The action is as follows:—The beam B is pivotted on a standard with a fulcrum at F, the arrow showing the direction of motion. When the current traverses the lamp, the plunger P, by virtue of the feed solenoid (not shown here), is brought down on the upper lug or end of the break-band *b*, the other end of which rests on the top of a pin which goes into the spring dash-pot D. The result is a tightening of the band round the periphery of the wheel W, which gives it a slight rotary motion, the effect of which is to separate the carbons. As the arc grows larger by the consumption of the carbons, the main solenoid allows the beam B to move in the opposite direction to the arrows, thus slightly loosening the grip of the break-band on the wheel, which is moved round by virtue of the chain *c* pulling on it, the chain *c* being attached to the upper carbon-holder, to which a gravity bias is given by the attachment of a small weight (about two ounces) fixed to the cross-piece supporting the carbon-holder.

With a 10-ampere current and E.M.F. of 50 volts it is impossible to see the "feed." In the ordinary or "parallel" burning Kent lamp there is but one wheel and one solenoid. For "series" running there is a second solenoid placed in "derivation" between

Digitized by Google

the "live" terminals of the lamp, which helps the action of bringing the carbons together should too little current be flowing through

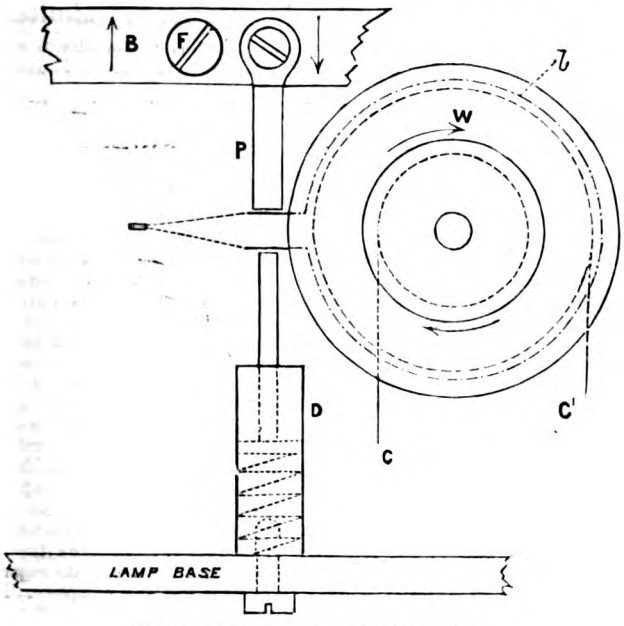

FIG. 1.—Diagram of the Brake Action.

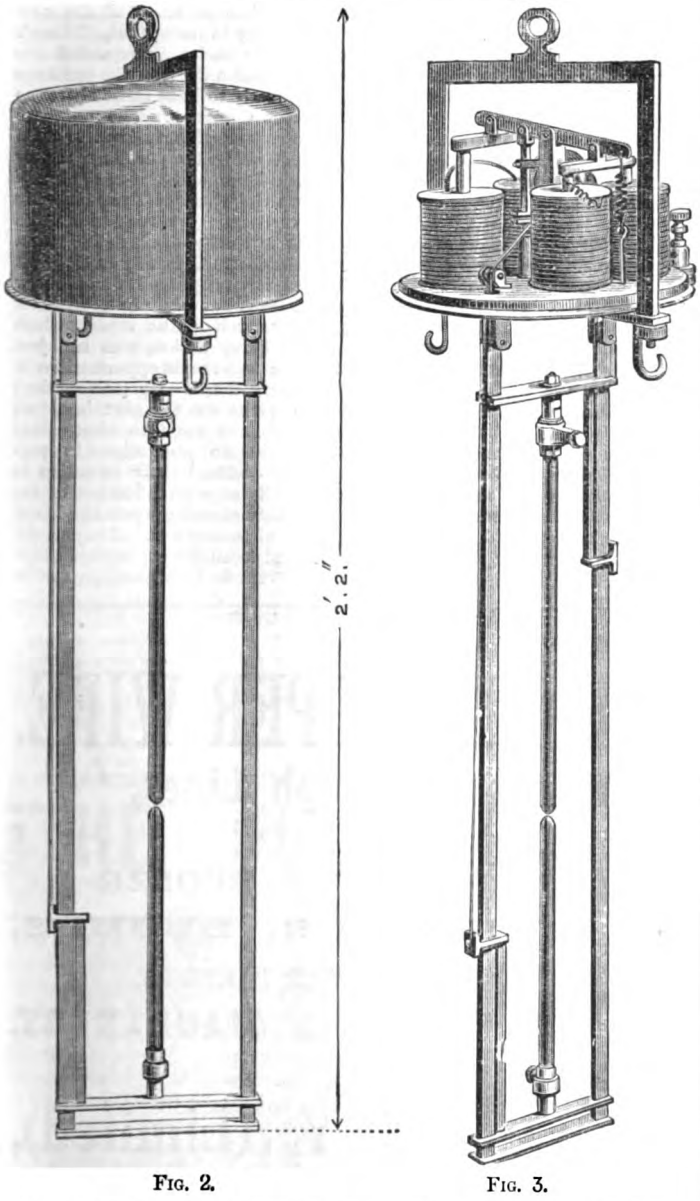

FIG. 2. FIG. 3.

the main series solenoid. The Kent arc lamp (Figs. 2 and 3) is now working on a 65-volt parallel "direct" circuit at "Olympia."

TRADE NOTES AND NOTICES.

Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

MESSRS. W. T. GOOLDEN AND CO. — We have received from this firm some lists relating to continuous-current dynamos, magnetic separators, electrical coal-cutting machinery, portable testing apparatus, and resistances for testing dynamos, motors, and accumulators for experimental purposes. They are in most cases accompanied by illustrations and particulars as to price, &c., and are in a handy octavo form.

MESSRS. J. H. HOLMES AND CO.—Amongst the lighting installations recently erected by this firm is that of the Home and Colonial Stores, near the "Angel," Islington. The light gives the greatest satisfaction to both proprietors and customers, the latter having frequently complained of the insufferable heat occasioned by the large number of gas jets necessary to light the large building. We think such an installation worthy a visit from the proprietors of other large stores and provision merchants, as at this season of the year such buildings are usually most uncomfortable promenades.

MESSRS. B. VERITY AND SONS.—At the last meeting of the Board of Guardians of the Strand Union, Mr. James Willing moved that the resolution passed on October 22nd last, deferring the acceptance of a tender for electric lighting for seven months, be rescinded ; and that the report of the General Purposes Committee, recommending the acceptance of Messrs. B. Verity and Son's tender, amounting to £92, be adopted. Mr. Emden seconded. A long discussion ensued, but the motion, on being put to the vote, was lost by a majority of one.

THE LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE. —We have received from this firm a neatly-printed illustrated pamphlet, giving full particulars of the Thomson-Houston systems of electric lighting. The pamphlet also contains particulars and prices of dynamos and transformers.

MESSRS. THOMPSON AND REW.—This firm announces that the partnership existing between Mr. N. G. Thompson and Mr. G. H. Rew terminates by the effluxion of time on November 30th, and that from that date the business will be carried on by Mr. Thompson.

MESSRS. W. O. ROOPER AND TOZER.—This is the title of a firm which has recently commenced business as electrical engineers at Greengate, Stafford, with a London office at Pelton-road, East Greenwich, S.E. From a circular just received we learn that the firm has successfully carried out a number of electric light installations, amongst which is the Café Monico, Piccadilly.

REMOVAL NOTICE.—Messrs. Perry and Co., makers of electroliers, &c., of 72, New Bond-street, London, W., will remove after Christmas to their new premises, 17, Grafton-street, Bond-street, London, W.

SCHMIDT-DOUGLAS ELECTRIC COMPANY (IN LIQUIDATION).— Creditors of this Company are required to send in full particulars of their claims to Mr. E. Musgrave, Chartered Accountant, Bradford, on or before December 21st next.

CATALOGUE OF THE ELECTRIC SUPPLY COMPANY (CHICAGO).— This is a bulky volume of considerably over 300 pages. The illustations and typography leave little to be desired, and the list of electrical supplies is most comprehensive, including Cardew voltmeters, Profs. Ayrton and Perry's hot-wire voltmeters, wire of all descriptions, incandescent and arc lamps, switches, artistic fittings, linemen's tools, tachometers, insulators, &c., &c. The last 50 pages are devoted to useful tables and formulæ.

SALES BY AUCTION.—The sale by Messrs. Wheatley Kirk, Price, and Goulty, of the entire contents of the Victorian Engine Works, Chester, has been fixed for December 11th next, at 11 o'clock prompt. Particulars will be found in our advertisement columns.

——— Mr. Joseph Dawe sells by auction this day (Friday) the Materials and Fittings belonging to Douse's Fire Check Company (Limited). The catalogue includes some electrical apparatus. The sale, which takes places at Harbrow's Building Yard, South Bermondsey, S.E., commences at 2 o'clock.

TENDERS WANTED.—The Directors of the Indian Midland Railway Company are asking for tenders for the supply of telegraph battery materials, sulphate of copper, and tube expanders, &c. The tenders must reach the office, 3, New Broad-street, E.C., not later that 12 o'clock noon, on Thursday, December 5th.

——— Similar tenders are invited by the Directors of the Great Indian Peninsula Railway, whose offices are at the same address.

THE GAS JOURNALS AND THE ELECTRIC LIGHT.—As a sign of the times, we may mention that several of our gas contemporaries have come to the conclusion that the moment has arrived when their columns should be open for the reception of advertisements and notices from the electric light supply and manufacturing companies.

COMPANIES' MEETINGS.

Brush Electrical Engineering Company (Limited).

The statutory meeting of the shareholders in this Corporation was held on Monday, at the Cannon-street Hotel, the Right Hon. Lord Thurlow in the chair.

The SECRETARY (Mr. Emil Garcke) having read the notice calling the meeting,

The CHAIRMAN said that the shareholders must all know by this time the circumstances under which this new Company had been formed. It was not only the Brush shareholders that he had now the honour to address, but those of the Falcon Engineering Company, and he thought he might almost say those of the Australasian Company, which had finally entered into an agreement with this Company, with certain modifications which were contemplated and explained at the last meeting. The Board consisted, as they were aware, of the Anglo-American Brush Directors, including a new member, the Duke of Marlborough, who was one of their oldest and most valued customers. The Duke had had the electric light introduced into his palace of Blenheim, as well as into his town residence in Carlton-terrace, and took the most lively interest in all electrical and engineering works, possessing an extraordinary amount of intimate knowledge in relation to both subjects, so that he (the Chairman) had no hesitation in saying that it would be difficult in a Company like theirs to find a more valuable Director than they had acquired in the person of His Grace. Besides the Brush Board, they had representatives of the two amalgamated companies. The nominee of the Falcon Engineering Works was Mr. Sanderson, who was present; and Mr. Van Tromp, who could not attend, and who was formerly the chairman of the Australasian Company, had joined them to represent the interests of the shareholders of that Company. As regarded their amalgamation with the Falcon Company, it was now complete. They had issued shares to the shareholders of the Falcon Company in the same way as they had issued shares to the old shareholders of the Anglo American Company. They had placed the debentures—£75,000—on the property of the Anglo-American Company, with debentures of the new amalgamated Company. They had had no difficulty in doing that, although naturally it took a little time and tact on their part. As regarded the shares which were to be obtained by the Australasian Company in exchange for their shares, the Directors were perfectly ready to issue those shares as soon as the patents had been assigned to this Company. The purchase agreement provided that shares in this Company should be issued to them to the extent altogether of £31,000—£30,000 being the purchase money and £1,000 representing the expenses of liquidation and the assigning of the patents. For that the Company acquired the whole of their rights in Australia, the Cape, and India. There was some deviation from the original scheme, which was to include also their assets—book debts, plant, and so forth. These were valued by the Australasian Company at £15,000. As the agreement had now been concluded, it was optional for the new Company to take over those assets up to the 1st of January next. Whether they would take them over would depend very much on the report which they would very shortly receive from Mr. Percy Sellon, who had just returned from Australia, where he would have had ample opportunities of ascertaining the value of the plant and book debts. He (the speaker) believed it to be true that a portion of the plant was to a certain extent obsolete, but Mr. Sellon would be able to inform them to what extent that was so. At any rate they were under no obligation to purchase the plant or book debts unless they declared their intention to do so before the date mentioned. That was the only modification of the scheme set before them. He thought they were entering upon the life of this new Company under the most favourable circumstances. They would have all the energy of the new Company added to all the experience which they had acquired in connection with their various undertakings, and he

thought it would be the fault of the Directors if they could not now conduct the affairs of the Company so as to return to the shareholders handsome dividends. Beyond that he thought it would be unwise for him to say more on that occasion. There was one point that he might perhaps enlarge upon with advantage, namely, the Falcon Works at Loughborough. They had taken over those works, and the more they saw of them the better they liked them. The Board were spending a certain amount of money in adding to them and connecting other portions to their own uses. They had not put away the branches of the engineering business which the Falcon Company had carried on. They had found on examination that that business was of a very remunerative kind, and they were now carrying on the manufacture of cars and locomotives originally conducted, and he might add that the tools and shops were admirably adapted for the manufacture of the various articles that the Company had to make for its own uses, namely, motors, dynamos, and various kinds of engines for driving electric lighting machinery. There was one other circumstance which induced him to look forward with very considerable satisfaction to the future, and that was the undoubted advance which electric lighting was making, not only in the metropolis, but throughout the whole of Great Britain and the civilised world. They knew that the Board of Trade was at the present time overwhelmed with work, and that it had under consideration 430 applications for Provisional Orders for electric lighting throughout the length and breadth of the land. When they considered what a vast amount of manufacturing of plant and machinery of various descriptions that must entail—and it might be reasonably hoped that the Company would get its fair share of the work—he thought they would have every right to say that it would be the fault of the Directors if they could not now bring the Company to success, and earn good dividends. The actual work in hand at the present moment of paying orders was more by a considerable quantity than the whole of the work they turned out during last year, and every day was bringing in fresh orders. Indeed, their only difficulty was to execute those orders. The works in Belvedere-road were fully occupied, as were also those in the country; and although they did not like to turn away orders, he was sorry that they had been occasionally compelled to do so during the last eight or ten weeks. Of course, it was necessary for the Company to endeavour to provide against such a misfortune, and they were lending their best energies to that end. These things could not be done without absorbing a large proportion of their working capital; but they all knew, as business men, that, if they did not invest their money in a concern, it was hopeless to expect to get anything out of it. They were engaged, however, in endeavouring to draw the correct line where to stop in the matter of getting increased facilities for manufacturing purposes, and the erection of shops. They had, he thought, the advantage on the Board of the advice and counsel of two or three very wise business men, and the shareholders might with some confidence rely on their judgment for drawing that somewhat delicate line at, perhaps, as near the proper place as it was possible to be done.

Mr. H. G. WEIR thought the shareholders must be very much encouraged by the remarks of the Chairman. He wished to know whether they took over from the Falcon Company any patents in connection with electric lighting. He further asked whether the principle of piece work or day work was adopted in the workshops, and whether the Directors had taken care to insert a clause to provide against strikes. What was the cost of electricity to-day as compared with it seven years ago?

The CHAIRMAN, in reply, said they took over no patents in connection with electric lighting. They did both piece work and day work. There were certain things that were manufactured under a system of piece work, and, as in the case of all shops and factories, there were other things that must be done by day work, so that a hard and fast line could not be drawn. As regarded strikes, the subject was one which they had long been in the habit of taking into consideration in contracting to deliver by a certain date. But strikes were not the only things which they had to provide against. There might be such an unavoidable occurrence as their premises being destroyed by fire. But all such risks were provided for in the usual way. As to the cost of electricity, it was a difficult question, and a general answer could not be given to the shareholder's question. At the present time labour was dear, iron was dear, and fuel was dear—much more so than they were some little time back. All these circumstances had to be taken into consideration; but, on the other hand, certain improvements were being made from day to day in the science of electricity which enabled them to do away with some of the costly processes of manufacture, and so on; and in whatever was being done in that direction they were in the forefront.

On the motion of Mr. WEIR, seconded by a SHAREHOLDER, a vote of thanks was passed to the Chairman and Directors, which the Chairman briefly acknowledged, and the proceedings terminated.

NEW COMPANIES REGISTERED.

AMERICAN ASBESTOS COMPANY (LIMITED).—This Company was registered on the 18th inst., with a capital of £50,000 in £5 shares, to acquire mines and lands in Canada and the United States of America. An unregistered contract of the 13th inst. will be adopted.

ECUADOR CENTRAL RAILWAY COMPANY (LIMITED.)—This Company has been registered to construct and work railways, tramways, lines of telegraph and telephones, in the state of Ecuador, or elsewhere. Capital £115,000 in £10 shares, of which 7,700 are Preference shares. The Company is registered by Messrs. Ashurst, Morris, Crisp, and Co., solicitors, 6, Old Jewry.

ORIENTAL ASSOCIATION.—This Company has been registered to take over, as a going concern, the business recently carried on at 16 and 17, Old Cavendish-street, under the name or style of "The Oriental Association," and also to carry on, at the same place or elsewhere, the business of an electric light company in all its branches. Capital, £5,000, in £1 shares, of which four are founders'.

CITY NOTES, &c.

BLACKPOOL ELECTRIC TRAMWAY COMPANY.—At the meeting of this Company, held on Saturday last, the report of the Directors, showing a profit for the year of £2,983, was presented to the shareholders. Out of this sum it was proposed to pay a dividend of 7 per cent., to put £1,350 to depreciation and reserve, and to carry the remainder forward. This was agreed to, and Messrs. Morris and Oddie were re-elected Directors.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 22nd amounted to £7,238.

INCANDESCENT GAS LIGHT COMPANY (LIMITED).—At a meeting on Wednesday it was proposed that the Company should be wound up voluntarily. As an amendment Mr. A. Carey moved, and Mr. F. L. Rawson, of the firm of Messrs. Woodhouse and Rawson United (Limited), seconded, that a committee of shareholders should be constituted for the purpose of conferring with the Directors with a view to the reconstruction of the Company. The amendment was adopted, and the motion therefore fell to the ground.

NATIONAL TELEPHONE COMPANY.—The National Telephone Company announce that the certificates for the recent issue of new shares are ready and can be obtained at the office, Oxford-court, London, E.C., in exchange for banker's receipt.

SPANISH NATIONAL SUBMARINE TELEGRAPH COMPANY (LIMITED).—The numbers are announced of 75 bonds, of £100 each, of this Company, which were drawn on Tuesday to be paid off at par on and after December 31st next.

STOCK EXCHANGE.—The Committee of the Stock Exchange have appointed Wednesday, December 4th, the special settling day for Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited), shares, Nos. 1 to 15,000. Application has been made to the Committee to allow the ordinary and Preference shares of the Brush Electrical Engineering Company (Limited) to be quoted in the official list; and to appoint a settling day in, and to grant a quotation to, the Electricity Supply Company for Spain (Limited), ordinary shares, and the National Telephone Company (Limited), additional shares, Nos. 386,876 to 436,700.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 22nd, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £5,203.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

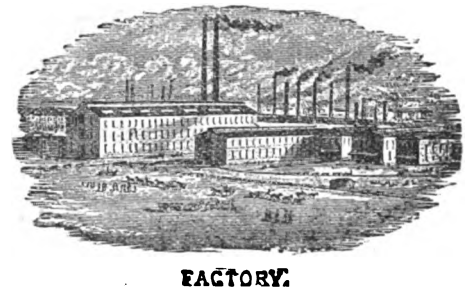
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.



FACTORY.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 603.—Vol. XXIV. FRIDAY, DECEMBER 6, 1889. Price Fourpence.

NOTES.

We have received the following cablegram from our New York correspondent, from which it will be seen that it is more than doubtful whether electricity had anything to do with the recent disastrous fire in Boston:

"The theory that the fire in Boston was caused by crossing with an electric light wire is being abandoned, as it was too late in the morning for the arc lights to be running. It is now *suggested* that it might have been caused by contact with electric railway trolley wires, but these wires are more than a mile away, and there is absolutely no evidence as to contact; moreover, they all have guard wires. *It is believed that the trouble with the time signalling wires was caused by the fire*, and did not itself create the fire. Mayor Hart, of Boston, in a communication to the aldermen, is not satisfied that the electric light wires caused the fire, but suggests that, as a guarantee or precaution for the future, safety fuses should be placed on every wire of every class."

Mr. Harness and his Medical Battery Company have lost their "qualified medical adviser," and are not likely to get another. The General Medical Council have ordered Dr. Leeson's name to be struck off the Medical Register "for infamous conduct in a professional respect," he having acted as "cover" for Mr. Harness in the business of a medical electrical practitioner. This is something to be thankful for, but not much. A man who did not scruple in such a business to employ and make the most of a duly qualified doctor, will experience very little difficulty in getting along without one. In the daily papers, only a week after the loss of Dr. Leeson, the electropathic Mr. Harness appears as brisk as ever to the tune of four columns of advertisement; and until the profession of journalism is protected by a Council similar to that representing the medical profession, Mr. Harness and the like of him will continue to thrive on the credulity of the public.

Electric meters depending on the rate of going of a clock, the balance or pendulum of which is electro-magnetically controlled by the current to be measured, are no novelty. The well-known meter of Aron is a mere modification of the meter of Ayrton and Perry, and this, again, is foreshadowed in the early chronographic galvanometer of Watkin. The main complaint against meters of this class is that they require frequent winding. In another column we illustrate a meter from which this source of annoyance is eliminated by the device of substituting slow-torsion pendulums for the ordinary rapid gravity pendulum. Clocks which require to be wound up once a year only are now becoming common in consequence of the introduction of torsion pendulums. The adaptation of the same device to the electric meter brings the apparatus one stage nearer to the requirements of the average practical man, who is still too apt to regard electricity meters as an impracticable fad.

Mr. Bernstein has been most indefatigable in his efforts to perfect his series system of supplying incandescent lamps. He has certainly had every opportunity of getting the system discussed, and probably it is very generally understood by this time. In this week's portion of his Paper will be found a very interesting and very neat proposed application of dynamotors, or motor-generators, as Mr. Bernstein's latest addition to his system.

By the arrangement, which we describe elsewhere, he undoubtedly makes a considerable advance in his system, as regards its applicability to cases where the number of lamps to be supplied is too great to be treated by the direct series connection of 10-ampere lamps. We commend this new feature to the careful attention of our readers. At one time—at the time when Mr. Bernstein brought his system before the Society of Telegraph Engineers—it appeared to us that for scattered districts it certainly possessed some advantages; but, so far, it appears to have failed to gain the confidence of the electrical community, and neither it nor any other system has ever seemed to be able to stand against the very powerful competition of the alternate-current transformer method of working. Whether in the case of Mr. Bernstein's system this has been due to the weakness of any one particular part of the apparatus—dynamo, lamps, line, or accessories—we do not know; but we see no reason to doubt that, with good and reliable lamps, this method could give a very fairly satisfactory account of itself on a moderate scale of working.

Probably the first idea of every electrical engineer who has come fresh to the consideration of the application of electric motors to tramcars, has been that the best place to put the motor was directly on the axle of the car; and it has only become the custom to interpose gearing because sufficient

Digitized by Google

power could not otherwise be obtained unless by the use of enormous motors. It is, therefore, with some surprise that we find a long account in the *Electrical World* of what is called the Baxter car-motor. The illustration shows a car truck fitted with this motor, which apparently takes much less room than an ordinary motor. Indeed, the truck presents the appearance of having no motor on it at all, but a careful inspection, and perusal of the description, reveals the fact that the motor is a kind of thin boxed-in disc on one of the wheels. We are favoured with nothing that merits the term description, so far as the motor is concerned, but are told that the designer claims to have obtained a very strong field in a very contracted space, and that by using on the armature a great number of turns of wire unusually large in cross-section he has secured a high efficiency and large torque. Unfortunately, our knowledge of the physical properties of materials useful in the construction of motors, and some acquaintance with the properties of motors when constructed, lead us to regard with a painful scepticism this latest claimant for our confidence. We do not assert that a tramcar with direct-driven axles is unattainable; but, knowing that well-constructed motors, geared down to an axle driven at a fraction of their speed, have to be forced up to their maximum output, we do say that any one has much to learn, and nothing to teach, who claims to obtain better results out of smaller apparatus driven at lower speed.

Amongst our editorial notes in the issue of November 15th, we commented upon a suggestion of Mr. N. Tesla for obtaining continuous currents from an alternating current. It now appears that devices of a somewhat similar order have been proposed by Mr. E. E. Ries. The devices of Mr. Tesla were of a more or less hypothetical character, and were not acccompanied by any results obtained in practice—indeed, some of them were open to serious doubt whether they could answer the desired end at all. To us it seems that some of Mr. Ries's suggestions are more practicable. One of them consists of a double alternate-current machine having two armatures differing by a half-period; the field-magnet is laminated, and acts as primary to the two armatures as secondaries. If now an alternating current is led around the field-magnet, and *if* the armatures are driven at precisely the proper synchronising speed, they will give off to their respective circuits direct currents. It is ingenious, but is it yet practical? A motor-dynamo to be actuated by alternate currents and to generate continuous ones is at least as practical, and was discussed on this side the water some years ago.

In another column will be found some "new views" upon telephonic disturbances by an American electrician. His experiments present several points of interest and of practical importance. The particular trouble to which our cousins give the quaint but expressive name of "cross-talk" is known in this country, and particularly in London, by the more high-sounding but less expressive name of "induction." As it happens, however, the greater part of the so-called induction troubles in London are due to a conjunction of two causes with which neither electrostatic induction nor electro-magnetic induction has anything to do, namely, a moist and smoky climate and the absurd use of shackle insulators at all possible places along the line. In other words, leakage, through films of dirt accumulating upon insulators of a wholly unsuitable pattern, is the real culprit.

Another cause of cross-talk, not alluded to by the author of the Paper in question, doubtless plays its part in the troubles usually assigned to "induction." We mean the practice of providing a common return through earth for all the radiating lines of a system. If the currents sent through a line flow back *vid* the earth, what is there to hinder a fraction of them from finding their way back through any convenient neighbouring line which likewise goes to earth? Indeed, this is what one would expect to occur. Metallic circuits, with clean insulators of a rational pattern, are singularly free from cross-talk. But the telephone folk throw the blame upon "induction" for all the faults inherent in their system.

The *Electrical World* of November 16th contains a description of a transformer devised by Dr. Leonard Paget, whose object is said to be to remove the reproach from transformers that they are very unequal in efficiency with varying loads. It is generally asserted that, although transformers may be very efficient with full load, they become much less efficient when the load is reduced. Of course the efficiency falls, but we believe that on comparatively light loads a very high percentage is yielded. Our readers will remember that Prof. Ayrton obtained very good results—something like 90 per cent. with one-third load—from a transformer which is probably neither better nor worse than others. Nevertheless anything that Dr. Paget or anyone else can do to give an efficiency equally high for all loads is to be welcomed. But from our reading of the description it appears that if Dr. Paget succeeds in getting a fairly equal efficiency with a considerable range of output, it is not the highest efficiency by any means. We take it that the best result at any and every load with any given transformer will be obtained by using the best magnetic circuit of which the material allows. But Dr. Paget's plan is to vary the magnetic circuit by moving its two iron portions in relation to one another, so that the best condition is obtained with the maximum load. At smaller loads the effect is not so good, the magnetic circuit having a considerable gap in it. From this it will be evident that Dr. Paget has not made a step in advance.

The London County Council is to be congratulated on having taken time by the forelock in the matter of a municipal testing laboratory. As will be seen in another column, £2,000 have been voted for the purchase of apparatus, and the Highways Committee has been empowered to acquire suitable premises. In deciding to appoint an inspector to supervise the main-laying operations at present in progress, the Council, in our opinion, acted very wisely. It is unfortunate,

Digitized by Google

however, that the magnificent salary of three guineas a week was attached to this important post. The entrusting of such onerous duties to an underpaid official does not seem to us either true economy or good policy.

At the last meeting of the Commissioners of Sewers the tender of the Brush Company for the lighting of the Central District of the City was accepted. It was *hoped* that at the next meeting of the Commissioners the question of the lighting of the East and West Districts would be settled. Meanwhile, the Brush Company, whose tender has been, and the London and Metropolitan Companies, whose tenders probably will be accepted, are proceeding with their applications for statutory powers. If these are obtained a pretty complication is promised, in view of the action of the City authorities in having granted electric lighting powers to these Companies without reference to the Board of Trade.

The financial results of the Blackpool electric tramway continue to be satisfactory to the shareholders and encouraging to the advocates of electric traction. Last year's dividend was 4 per cent., this year it is 7 per cent.—£1,350, as against £1,000, being placed to the reserve and depreciation fund, and £235, as against £56, being carried forward. The totals, it is true, are small; but the figures, nevertheless, show plainly what can be done by the adoption of electric traction.

Two occurrences of St. Elmo's fire have turned up during the past week. One of these is a narration of the appearance of the phenomenon at an English east-coast watering place on November 20th last. The other is a brief reference in that extraordinary letter addressed by the Mahdi to Emin Pasha, bidding him to surrender in the name of Allah and the Prophet. Amongst the proofs cited by the Mahdi of the Divine origin of his power is the statement that tongues of fire appeared upon the tips of the spears of his soldiers.

The fire upon the spears of the Mahdi's soldiers is not without historical parallels. According to Procopius, the lances of the soldiers of Belisarius emitted sparks when they were preparing to advance against the hordes of the Vandals. And Cesar narrates how during his African campaign the twin gods Castor and Pollux descended in the form of fire, which streamed from the spears of his famous fifth legion in promise of his victory over the followers of Pompey.

In these days, when nothing is sacred to the man with a camera, photographs of lightning flashes have become quite common. Who will be the first successful photographer to "codak" the fire of St. Elmo?

The official journal of the Spanish Telegraph Department (*Revista de Telegrafos*) contains a report, dated November 12th, of some very remarkable long-line demonstrations in that country of the utility of the Phonopore telegraphs of Mr. Langdon Davies. From Madrid to Saragossa, a distance of 550 miles; from Madrid to Barcelona, a distance of nearly 1,000 miles; and from Madrid out and home through Saragossa, Barcelona, Tarragona, and Valencia, a distance of over 1,100 miles, were the principal circuits employed. Over these distances a diplex and duplex service was established, without the least difficulty or hitch, upon the ordinary telegraph wires, a triplex acoustic service being also superposed upon the same line. The instruments used in the duplex and diplex services were the Phonopore Morse printer, employing the usual method of dot-and-dash on tape. The Spanish telegraph officials, who appear to have been highly gratified with the success of the demonstrations, attest that the transmission was perfect. These demonstrations constitute a departure in harmonic telegraphy that promises to become of utmost importance in the immediate future. The fact that they took place on actual lines of a greater length than the distance from London to Caithness adds to the significance of the achievement.

We call the attention of our readers to the column of Trade Notes and Notices which now appears at the end of this journal, and which will form in future one of its regular features.

Stockton.—Last week the Town Council decided to apply for a Provisional Order for power to supply the electric light.

The Italian Government and the Telephones.—It is reported that the Italian Government intends to take over the telephones.

Paris-Nantes Telephone Line.—It is proposed to erect a trunk wire between Paris and Nantes, a distance of about 250 miles.

Interruption of the Calais-Fano Cable.—The Danish cable is interrupted at a point in the North Sea about 70 miles from Calais.

The Central Station at the Halles Centrales.—This station was opened on Sunday last by M. Yves Guyot, Chairman of the Paris City Council.

Bath.—At a special meeting held last week the Town Council unanimously gave their sanction to the application by Mr. Massingham for a licence.

A Correction.—On p. 86, line 22, of Mr. Bernstein's Paper last week, read "100 volts and ·6 ampere," in lieu of "100 volts and 6 amperes," as printed.

Telephonic Extension.—Portsmouth, Southampton, and Winchester are now in telephonic communication, and the trunk line is about to be extended to Bournemouth.

London County Council.—At the meeting on Tuesday Mr. G. Clement Dunscombe, the city engineer of Liverpool, was elected engineer of the Council, at a salary of £1,500.

Gas Companies and the Electric Light.—The Luton Gas Company and the Sutton, Southcoates, and Drypoole Gas Company are seeking powers to generate and supply electricity.

Municipal Lighting in South Australia.—A Bill is about to be introduced into the South Australian House of Assembly authorising Corporations to erect gas and electric light works.

Postal Telegraph Revenue.—The total receipts from the Telegraph Service paid into the Exchequer from April 1st to November 30th of the present year amounted to £1,550,000, against £1,400,000 for the same period of 1888.

Rise in the Price of Indiarubber.—The price of all qualities of indiarubber has within the last few months risen considerably, and its market value is now double what it was a year ago. The stock in hand is limited, and the supplies continue to fall off.

Digitized by Google

The Sheffield Telephone Exchange.—This Exchange recently passed through its switch room over 69,000 messages, and of these 12,830 occurred in one day. As the Exchange numbers only rather more than 600 subscribers, this may fairly be considered to beat the record.

Fareham.—A largely-attended meeting of gentlemen who have applied for shares in the Fareham Electric Lighting Company was held last week at the residence of Mr. J. Blake. Resolutions were passed to at once register the Company, it having been announced that over 4,000 shares had been applied for.

Local Authorities and Overhead Wires.—In addition to the London County Council, the following Local Authorities seek powers by private Bills to build subways and deal with overhead wires—The Corporations of Bootle, Tunbridge Wells, Walsall, and Sheffield, and the Fleetwood Improvement Commissioners.

Kimberley.—Messrs. Gibson Bros., of Kimberley, South Africa, have obtained from the Town Council a concession for electric lighting in that place. The term is 21 years, and the price to be paid is 1¾d. per lamp per hour. The contractors undertake to be in a position in 18 months from the date of the concession to supply 3,000 lamps, if required.

Barrow.—The General Purposes Committee of the Town Council has decided not to proceed at present with a Provisional Order for the supply of electricity within the borough, and they have also decided not to give their consent to the application of those companies who have already given notice of their intention to apply for Orders. The Corporation owns the gasworks.

Lecture on the Electric Telegraph.—A lecture on the electric telegraph was delivered last Tuesday evening by Dr. Oliver Lodge at the Rotunda Lecture Hall, Liverpool. There was a large audience, which listened with deep attention and interest to an exceedingly lucid explanation of the principles of the telegraph. The lecture was illustrated by a series of interesting experiments.

Royal Society.—Among the Papers down for reading yesterday were the following:—O. Wiener and W. Wedding, Remarks on Mr. A. W. Ward's Paper "On the Magnetic Rotation of the Plane of Polarisation of Light in Doubly Refracting Bodies." H. Tomlinson, F.R.S., "The Internal Friction of Iron, Nickel, and Cobalt, studied by means of Magnetic Cycles of very Minute Range."

Dundee.—An adjourned meeting of the Electric Light Committee of the Town Council was held on Tuesday, when Dr. Hopkinson, who made a tour of the city the previous day, reported verbally the cost of supplying the electric light to the central portion of the city. He expressed the opinion that with an installation of 5,000 lamps the electric light would be quite as cheap as gas.

Electricity in Mines.—On Saturday last a Paper on "The Application of Electricity for Mining Purposes" was read by Mr. T. Vaughan Hughes to the North Wales Branch of the National Association of Colliery Managers at Wrexham. There was a large attendance. Sir Evan Morris presided, and congratulated the colliery managers that they had come together to hear something about electricity.

Newcastle.—At the last meeting of the Town Council, the agreements with the Newcastle-upon-Tyne Electric Supply Company, and the Newcastle and District Lighting Company, permitting them to proceed with their works pending the granting of their licences by the Board of Trade, were presented for sealing. The agreements give the Corporation complete control over all matters in connection with the streets. The sealing of the agreements was agreed to.

Madrid.—A company called the Compania Madilena del Electricidad has just been constituted at Madrid, with a capital of 3,000,000 pesetas (£112,000). Among the directors are Messrs. Rathenau, Siemens, and Grimner, of Berlin. The plans of the new company, as also the new buildings, machines, and lighting installations, have been ordered of the Allgemeine Electricitäts-Gesellschaft. The enterprise is favourably commented upon by the Spanish newspapers.

The School of Electrical Engineering and Submarine Telegraphy.—On Friday last a special lecture was delivered at this School to the students and their friends, by Mr. E. T. Carter (one of the staff), entitled "The Life of the late Dr. Joule, and his Work in Relation to Electrical Engineering." A reference was made to the movement in Manchester for a memorial to Dr. Joule, and various experiments and specially-prepared lantern photographs and diagrams illustrated the lecture.

Fenton.—At a special meeting of the Local Board last week, a resolution was passed deciding that notice should be given to the Board of Trade of the intention of the Local Board to oppose the grant of a Provisional Order to the Midland House-to-House Electricity Company and the Municipal Electric Light and Power Company, the reason for this opposition being the large stake the Local Board has in the existing gasworks. The Board also say that they are ready to supply electricity when occasion demands.

The Copper Market.—The stock of copper in sight now, according to Messrs. H. R. Merton and Co.'s monthly statistics, is a trifle under 100,000 tons. This is the lowest point touched since March last, when the total was 124,876; but is higher than at the end of November, 1888, when the stock was 97,906 tons, and more than double what it was in November, 1887—viz., 45,121 tons. The deliveries last month—which had only thirty days—were 13,415 tons, being nearly as good as in October, which had thirty-one.

Mustard Oil as a Lubricant.—Mustard oil has of late been given some attention as a lubricant, and it is reported to have been successfully used for some time in Germany for lubricating purposes. It is said not to be susceptible to cold, and besides does not easily become rancid or form fatty acids which would attack metal. Its lubricating value, moreover, according to Prof. G. Herman, of Aix-la-Chapelle, is of a relatively high order. No particulars have been yet given as to the cost of the new lubricant, its specific gravity, &c.

Edinburgh Exhibition.—There is every prospect, we are informed, of French electrical firms being well represented at the Exhibition. It is understood that the French Government will undertake the transport of French goods to and from Edinburgh, and that something like 120 electrical exhibits may be expected from France and Belgium, some of them on a large scale, the terms granted to the exhibitors by the Exhibition authorities being exactly similar to those accorded to English exhibitors through the London Chamber of Commerce.

The Late Sir Daniel Gooch.—Probate of the will, with codicils, made in June, 1887, and June, 1888, of the late Sir Daniel Gooch, Chairman of the Telegraph Construction and Maintenance Company, has been granted to the acting executors, his son, Sir Henry Daniel Gooch, and Mr. Thomas Mark Merriman, power being reserved to grant probate to the testator's brother, Mr. William Frederick Gooch, and to his son, Mr. Charles Fulthorpe Gooch, also named as executors in the will. The value of the personality is declared at £653,492. 1s. 1d.

Copper and the Electric Light.—At the annual meeting, yesterday, of the Copiapo Mining Company, Mr. Arthur Holland (the Chairman), speaking of the prospects of the copper market, said that he was connected with several electric lighting companies, and that he foresaw an immense consumption of copper for wires and ribbons. He was told that a mile of the copper ribbon required a ton of the metal. He thought that it was partly owing to this increased demand for copper that the "visible supplies" had gone down so rapidly, the monthly consumption being enormously increased.

Telephonic Extensions in the West of Scotland.—Telephonic communication has been established between Glasgow and Largs; and Skelmorlie, it is expected, will be similarly connected in a week or two. For the convenience of firms in the districts round Airdrie and Wishaw, the National Telephone Company has resolved to open exchanges in these towns on an early date, with communication to all the existing system. A new direct trunk wire from Glasgow to Dundee is now nearing completion, and an alternative and more direct route for the Edinburgh-Glasgow trunk wires has been arranged for.

Digitized by Google

The Hopkins Prize.—The Hopkins prize has been adjudged to Mr. R. T. Glazebrook, M.A., F.R.S., Fellow of Trinity College, for his researches in physical optics. The prize is adjudged by three Fellows of the Cambridge Philosophical Society, nominated by the Council of the Senate once in three years, for the best original memoir, invention, or discovery in connection with mathematico-physical or mathematico-experimental science. This is the sixth award of this prize, the former recipients being Prof. Stokes, the late Prof. Maxwell, Lord Rayleigh, Sir W. Thomson, and Prof. G. H. Darwin.

Aberdeen.—At a meeting of the Gas Committee of the Aberdeen Town Council last week, it was reported by the Town Clerk that the Board of Trade had stated, in reply to a communication which had been addressed to them, that they were not prepared to give any powers by Provisional Order except those strictly within the lines of the Electric Lighting Acts, and that they had also signified their intention of discountenancing all applications by way of special Acts. It was suggested at the meeting that the various Scotch Corporations should make a combined application to the Board of Trade with the view of urging them to bring in a Bill next session to amend the Electrical Lighting Acts and remove the anomaly which prevents the Local Authorities from making electric light undertakings part of their gas undertakings.

Telephone Soiree in Manchester.—A musical *soirée* and ball took place on Tuesday last week at the Manchester Athenæum to commemorate the recent marriage of Mr. Kenneth MacIver, manager of the Manchester district of the National Telephone Company (Limited). There was a large gathering. In the course of the evening the presentation of a gold repeater hunting watch to Mr. MacIver, and a pearl and diamond ring and a silver tea service to Mrs. MacIver, was made by Mr. H. P. Hughes, on behalf of the staff and business friends. Mr. Hughes pointed out that Mr. MacIver had the longest record of any telephone official in the United Kingdom. The subscribers and business friends held Mr. MacIver in high esteem, and there was a bond of friendship between the manager and the staff. Mr. MacIver briefly returned thanks on behalf of himself and his wife.

Proposed Memorial to Dr. Joule at Manchester.—A public meeting was held last week in the Town Hall, Manchester, for the purpose of considering the proposal to erect a memorial to the late Dr. James Prescott Joule. There was a large attendance. The Mayor of Manchester presided, and in his opening remarks spoke of Dr. Joule as a man whom the citizens of Manchester were proud to call one of themselves. Mr. Oliver Heywood moved:—"That this meeting desires to mark its deep sense of the benefits conferred on mankind for all time, as well of the great honour which has accrued to this district, by the scientific work of the late James Prescott Joule, by the erection of a durable memorial of him in Manchester, in the form of a white marble statue." Sir H. E. Roscoe, M.P., seconded the motion, which was adopted. A committee was appointed to raise, by public subscription, a sufficient sum to carry the resolution into effect.

Obituary.—We regret to announce the death, at Shanghai, on November 13th, of Mr. L. M. Holst, the Great Northern Telegraph Company's engineer in the Far East. Mr. Holst entered the company's service in China in 1874, and took an active part in all the company's first attempts to construct land lines and introduce inland telegraphs in the Celestial Empire, until he finally, in 1881, succeeded in completing the construction of the first inland Chinese telegraph line of any importance between Shanghai and Tientsin. Several routes were surveyed and many lines built under Mr. Holst's immediate supervision, and in recognition of his valuable services the Chinese Government decorated him with the insignia of the Double Dragon. In 1885 Mr. Holst was promoted to the post of superintending engineer in Shanghai to the Great Northern Company, which position he held until his death at the early age of 39.

The Lighting of the City.—On Tuesday last a report of the Streets Committee was presented to the Commissioners of Sewers, recommending that the tender of the Brush Company for lighting the Central District should be accepted. The Committee hope to be able to bring up a report at the next meeting dealing with the districts east and west. The contract is for 21 years, terminable at the end of 7 or 14 years, and the price £26 per annum for arc lamps. Mr. Pannell said, having been intimately associated with this question since it was first discussed in the Commission seven or eight years ago, he would like to say that he thoroughly agreed with the recommendation of the Streets Committee. He thought there could be no further objection, as their own requisition was acceded to. They ought to show that they really meant to give these people an opportunity of pressing forward electric lighting in the City of London. The report was adopted.

The London County Council and Electric Lighting.—At the last meeting of the London County Council Mr. F. Westacott brought up a report of the Highways Committee on the subject of electric lighting. The committee recommended—(*a*) That the Highways Committee be authorised to obtain premises suitable for an electric testing station; and also to obtain and fix, at a cost of about £2,100 the necessary apparatus for the station. (*b*) That a competent person be appointed, at a salary not exceeding £200 a year, to discharge the duties of inspector under the Electric Lighting Acts. (*c*) That a person be appointed, at a salary of £2 a week, as caretaker of the electric testing station, and to attend to the accumulators and otherwise assist the inspector. The report further stated that there was at present no means of ascertaining that the conditions imposed by the Council upon the electric lighting companies with regard to the laying of mains were complied with; and the committee were of opinion that a person should be employed to supervise the works of the companies with a view to insuring such compliance. They recommended that a person be appointed at a salary of £3. 3s. a week, to supervise the works of the electric lighting companies in the public streets. The report of the committee was approved.

Proposed Electro-Technical Exhibition at Frankfort.—The idea of holding an electro-technical Exhibition in Frankfort next year, to which we referred in our last issue, has, we are informed, met with the greatest approval, and the undertaking has the best financial prospects. Plenty of space, 538,000 square feet, is at the disposal of the Committee, as it has been found possible to make use of the site of the old railway stations. A special railway line right into the Exhibition will provide a cheap and easy means for the transit of exhibits. The Committee will thus be able to reduce the expenses of the exhibitor to a minimum, and will take care to provide the necessary motive power. As the Exhibition will be an international one, the Committee will endeavour to procure further facilities for the exhibitors by trying to obtain a reduction of freight and duty, in order to induce a universal participation in the enterprise. The Exhibition will include all branches of the electrical science and industry, but only those exhibits will be admitted which show a decided improvement on those of the last special exhibitions at Munich and Vienna. The Exhibition will open on June 1st, and remain open until the last day of October, 1890. It is proposed to divide the exhibits into the following 12 great groups:—(1) Motors for electro-technical purposes, such as steam, water, air, gas engines, &c., steam generators, &c., accessory apparatus; (2) Generators of electricity; (3) All kinds of apparatus for conducting and distributing the electric current; (4) Accumulators, transformers; (5) Devices for transmission of electric energy and its employment for industrial purposes; (6) Electric light and a special section for fittings of all kinds; (7) Telegraphy, telephony, safeguards against lightning, fire, theft, and other dangers, telegraphic fittings for houses, hotels, &c.; (8) Electrical appliances and apparatus for railways, tramways, ships, and nautical science; (9) Electrolysis, electro-metallurgy; (10) Electric apparatus for scientific, measuring, optical, acoustical, and school purposes; (11) Electro-therapeutics, electro-surgery; (12) Electrical literature. For Europe notice of participation should be given before December 20, 1889, and for other countries not later than January 15, 1890. All notifications should be sent to Mr. Leopold Sonnemann, editor of the *Frankfürter Zeitung*, Frankfort-on-Maine.

REVIEWS.

The Alternate Current Transformer in Theory and Practice.

By J. A. Fleming, M.A., D.Sc., Professor of Electrical Engineering in University College, London, &c., 8vo., 487 + xii. pp. (London: "The Electrician" Printing and Publishing Company, Limited, 1889.)

All that comes from the pen of Prof. Fleming claims double attention from the fact that its author not only possesses a thorough training in the theory of electricity, but also is continuously in touch with the practical everyday experience of a large electrical manufactory. He is also a master of the art of expressing himself in a manner which a student can follow, and does not wrap up his meaning in clouds of obscurity requiring the intervention of an interpreter to make his words intelligible. His former literary venture, the "Short Lectures to Electrical Artisans," gave a promise of still greater things to come, a promise not disappointed in the quality of the present work. The aim of the reviewer is not to puff a friend's wares on the log-roller's plan, nor to condemn without measure as though he were a disappointed rival, nor yet to make the review a sort of metaphorical trapeze upon which to display his own feats of literary gymnastics; his aim should rather be, on the one hand, to assist the reader to arrive at a judgment whether it is worth while for him in his particular case to purchase or consult the work, and, on the other hand, to assist the author to ascertain how far his work meets the needs of those for whom he writes, and in what way his work can be improved or developed. Incidentally, a review may serve other useful purposes, such as the commendation of helpful innovations, the exposure of popular fallacies, the condemnation of unworthy or obsolete matter, the recognition of merits in forgotten workers, or the criticism of hypotheses which are not yet established upon a basis of actual proof.

It would be very difficult to pick out from amongst the electrical literature of the past ten years any work which marks, as emphatically as does Dr. Fleming's book, the manner in which the practical problems of the day have compelled electrical engineers to advance in their knowledge of theoretical science. In 1884 Lord Rayleigh, as President of the British Association, remarked, in his inaugural address at Montreal, that the introduction of powerful alternate-current machinery was "likely to have a salutary effect in educating practical electricians whose ideas do not rise easily above ohms and volts." The educating influence of alternate-current working, compelling as it does the consideration of problems in the self-inductive action of a current as a factor of at least equal importance with that of the "resistance" of the circuit has been enormous. The fact that the presence of self-induction might, and would, entirely vitiate the readings of a measuring instrument if used on an alternate-current circuit, though when used with direct currents its readings might be perfectly accurate, was a fact which could not be disregarded from the commercial point of view. The strange paradox that in an alternate-current circuit the sum of the currents in two branches of a main might exceed the quantity of current in the main itself was no less true than it was puzzling. Even the simple facts of mutual-induction were almost as little recognised as those of self-induction. The fact that you could draw from the secondary circuit of a transformer a larger number of amperes of current than were supplied to the primary circuit of the transformer by the mains seemed so impossible to the official experts of the United States Patent Office, that they refused to grant a patent to a well-known inventor for an apparatus which should accomplish this now common transformation. This was in 1883. Nevertheless, the same Patent Office which had refused the grant to Mr. Bernstein on the ground of impossibility, issued a patent in 1886 to Messrs. Gaulard and Gibbs for the same thing. It was, therefore, a happy thought of Dr. Fleming to prepare a Treatise which should embrace the consideration, from both the theoretical and the practical aspects, of the transformation of alternating electric currents, beginning virtually where the ordinary simple text-books leave off, and going down *au fond* into those all-essential questions of self-induction, mutual-induction, periodicity, retardation of phase, virtual resistance, and square-root-of-mean-square value, about which neither the ordinary telegraph engineer nor the old-fashioned untrained electrician knows anything, for the simple reason that they do not come within the range of his practice. That the employment of a periodic or alternating current, instead of one of steady uni-directional flow, should almost totally alter the aspect of the phenomena, is due to the fact that when a current, instead of remaining steady, is changing its strength, the changes of strength (and, therefore, the strength itself) are governed not so much by the so-called passive "resistance" of the circuit as by the reactive effects of the magnetic "field" which the current sets up in the space in the neighbourhood of the circuit. The presence of this magnetic action in the surrounding space acts as a sort of invisible fly-wheel on the current, endowing it with a species of electro-magnetic momentum, by virtue of which any change in the strength of the current evokes an active opposing tendency. Dr. Fleming speaks of this property as electric inertia, a not inapt term provided it be remembered that inertia is a property tending to oppose the stopping of that which is moving, as well as to oppose the moving of that which is at rest. It should also be remembered that the so-called electric inertia is due to the presence of the magnetic field or vortex around the current, and should perhaps more strictly, at least in the present state of science, be termed "electro-magnetic."

As yet Dr. Fleming has only published the first volume of his treatise, dealing with the general facts about periodic currents and their induction, and the methods of calculation applicable to them. In the second volume, which will be eagerly awaited by those who have worked through the first, are to be considered the construction, design, and use of induction transformers, the practical measurement of periodic currents, and their application in lighting, welding, and other technical work for which they are suitable. The subject of the design, construction, and theory of alternate-current dynamo machines does not enter into the scheme of the book, an omission which may be readily supplied from other existing works, and which lightens the present work, and enables the whole space to be devoted to the immediate subject in hand.

Dr. Fleming's book begins with a short introductory chapter devoted to the narrative of Faraday's "ten days of splendid and conclusive experiment" in the autumn of 1831, by which he established the main facts about the induction of currents in closed circuits by varying the number of magnetic lines that thread through the space enclosed by the circuit.

The second chapter, on electro-magnetic induction, is of extreme importance, and comprises three main parts: the first dealing with the facts and definitions about magnetic forces; the second with the elementary facts about induction of currents, self-induction in circuits, and the use of coefficients of self-induction; the third part with magnetic hysteresis.

Dr. Fleming is very careful to make his readers think about the so-called lines of magnetic force as corresponding to something more than a mere mathematical conception. He points out how in Faraday's own mind the notion of a "line of force" grew from being a mere geometrical conception until it came to connote not merely a line or direction in space, but a definite physical magnitude, which, though associated with the notion of direction, was also associated with the notion of the product of a certain area of space into a certain average intensity of force over that area. In fact, to put the thing into mathematical language, he came to regard the "line of force" not simply as a "vector" quantity possessing direction *and* magnitude, but as a quantity which was itself of the nature of a surface integral. A simple simile will render the matter clearer. Consider the smoke which ascends a chimney and emerges, spreading into the air above. Consider any cross-sectional area drawn across and around the flow of smoke, either in the wider or the narrower part of the chimney, or in the still wider space above. The total flow of smoke across any such area is the same. The stream-lines of flow of the smoke are sometimes nearer together, sometimes wider apart. The density (or intensity) of the flow of the smoke will not be equal over

Digitized by Google

all portions of any one of the areas considered. Consider any small area which forms part of the old area, there will be a certain average intensity of the flow through this small area. Form the product of the small area into the intensity of the normal flow through it. Then the sum of all such products for all the small areas comprised in the total area may be called the surface integral of the flow, and it is obviously the same thing as the whole quantity of the flow through the area considered. Some writers speak of tubes of induction, or tubes of force, rather than of lines of force; the notion conveyed by the word "tube" being a little more graphic in leading to the conception of the flow through space of a something possessing a physical existence. The whole space in a magnetic field may thus be regarded as being divided up into a set of contiguous tubes of induction, and each tube containing space enough for a single magnetic line to run down its axis; but, as Dr. Fleming remarks, it is simpler in thought to disregard the tubular system, and to speak simply of the lines of induction, or lines of force. Dr. Fleming does not attempt to inflict upon his readers any fine-spun distinctions between lines of magnetic force and lines of magnetic induction, as some ultra-precisians have done. It is true that owing to the peculiarities of grain, &c., in iron, and indeed in all media which are not entirely isotropic (or which, in plain English, have a grain in any direction in their structure), the direction of the lines of magnetisation in the stuff does not always coincide with the direction of the lines as they would have been had there been no such grain. Some people call the lines as they actually are, lines of induction, and the lines as they would have been (if unaffected by grain) lines of force, and then proceed to tell you that though lines of force and lines of induction are not the same thing, they coincide in the case of isotropic media. No doubt such people would smell heresy in Dr. Fleming's use of the two terms as synonymous. The path of a line, or group of lines, of magnetic force is called a magnetic circuit; and the total quantity of magnetic lines in a circuit, considered as passing through a sectional area of the circuit, may be expressed, according to Dr. Fleming, in any one of the following ways, which all signify the same thing:—

"1. The number of unit tubes of induction passing through an area.

"2. The number of lines of force (induction) passing through an area (Faraday).

"3. The (total) magnetic induction through an area (Maxwell).

"4. The *flux* or flow of magnetic induction through an area (Mascart and Joubert).

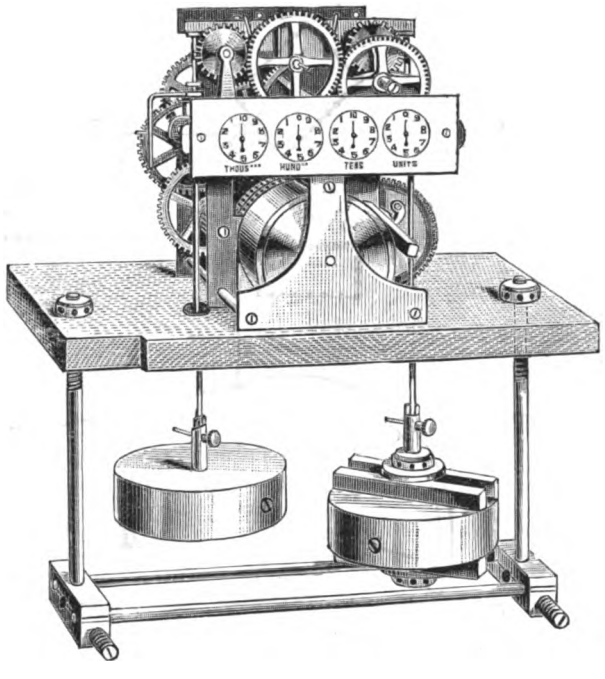
"5. The surface integral of magnetic induction over an area."

(To be continued.)

THE OULTON-EDMONDSON ELECTRICITY METER.

The Oulton-Edmondson meter, which is manufactured by Mr. Joseph Edmondson, of Bradford, consists of a clock having two independent torsion balances, or torsion pendulums, which are set to vibrate identical time when no current is passing. One of the balances carries two or more permanent magnets placed astatically; above, between, or beneath which is a conductor, carrying the current to be measured. Before the clock is started, and when the escapements are at the zero point, the magnets stand at right angles to the conductor. When the clock is running, and the current is passing along the conductor, the latter exerts a quickening or retarding influence upon the magnet-carrying balance, according to the direction of the current. The difference between the speed of the magnet-carrying balance and the other balance is recorded on dials, through a differential gear of novel construction and a registering train. The balances are set to the rate of about 15 vibrations to the minute, and the instrument is calibrated to give a variation between the time of the two balances of one vibration per hour for one ampere-hour, and the readings are proportional to the current through a very wide range. It will measure the smallest current. The meter is calibrated in ampere-hours, each division of the units' dial indicating 10 ampere-hours, or one Board of Trade unit if the E.M.F. be 100 volts. One of the wheels in the registering train is a "change wheel." It has 100 teeth (corresponding with an E.M.F. of 100 volts), and can be changed for one with any other number of teeth up to 120, when the register will indicate B. T. units at an E.M.F. corresponding with the number of teeth in the wheel. This change-wheel is, therefore, termed "the volt-wheel." The meter is contained in a wooden case., measuring 15in. high, 13in. wide, and 6½in. deep, and the whole apparatus is exceedingly compact and portable.

It possesses several advantages over other meters which measure the current by the difference set up in the time of two clocks. It is much more compact. The balances being parts of one clock, and being driven by opposite ends of one and the same spring, are less liable to set up a difference of time than if belonging to two separate clocks, and therefore driven by two separate springs. Only one winding is required, and if the clock be allowed to run down for want of winding, both balances stop together, instead of one of them going on and registering at a great rate for or against the consumer, as has sometimes been the case in meters consisting of two separate clocks. By



The Oulton-Edmondson Meter—Front View, with case removed.

using "torsion" balances the clock can be run at a very slow speed, so as to require winding up only at long intervals. It can be made to run for any time from three months to one year. The torsion balance is so suspended as to be little, if at all, affected in its action by external vibrations, and it will work satisfactorily in positions in which a pendulum would be stopped.

Variations of temperature equally affect *both* balances, and consequently do not affect the record, as only the *difference* of time between them is registered. The use of magnets mounted astatically tends to preserve their magnetism from variation, and reduces the range of external influences. The loss of E.M.F. in measuring the current is inappreciable in its passage through the short straight conductor, which gives ample force for the measurement.

The calibration of the instrument is easily affected by passing a constant current through the copper rods, and varying their distance from the magnets. To convert the meter into a wattmeter we have, of course, only to substitute fine wire coils for the permanent magnets, in which case the instrument can be used for alternating as well as continuous currents.

ON THE DISTRIBUTION OF ELECTRIC ENERGY BY MEANS OF CONSTANT CURRENT.

BY ALEXANDER BERNSTEIN.

(*Concluded from page 87.*)

We continue this week our translation of the Paper read before the Electrotechnical Society of Berlin by Mr. Alexander Bernstein.

The system as described here has already met with considerable success, although many of the details have only lately been brought to their present perfection. For the lighting of large areas it is not possible to devise a simpler arrangement, which is at the same time so easily superintended. To this must be added the cheapness and the small loss of energy in the conductors, and the high efficiency of the lamps. It is, therefore, easily seen that such a system was sure to prove useful for the lighting of large factories, mines, stations, streets, and similar cases. For the latter application the use of glow lamps has the additional advantage that the light can be regulated from the central station according to the requirements of the various hours of the night, which is not possible with arc lamps. I may add the remark that the practical advantages of the system have already shown themselves in cases in which the question of distance did not come into consideration at all. However, the number of lamps which can be placed into a single circuit of this kind is limited, as otherwise the total tension would be too high. In regard to the tension, which may be admitted, we must, of course, make a difference between a series and a parallel system: in the latter case the maximum tension exists all over the plant; in the series system the maximum tension is only on the terminals of the dynamo. According to my experience I am inclined to consider a tension of 1,500 volts on the dynamo as perfectly safe; this, however, depends somewhat on the place in which the lamps are to be used, and no general rule can be laid down. In the United States it is now the custom to use twice this amount of tension; but I doubt whether it has been a wise thing to go as far as this, and I think it would be well to consider 1,500 as a limit, in order to insure good insulation, which is the necesary condition of safety. Under these circumstances, the number of lamps which can be placed in one circuit is limited; and if we have to place a large number of lamps, it is necessary to divide the whole plant into several separate circuits, each of which has the form shown in Fig. 1. This has certain advantages. The larger number of engines and dynamos, each of which may be connected to any of the circuits, are a safeguard against breakdowns; but if we have to deal with very large installations, such as are required for the lighting of towns and private houses, a system of this kind would hardly be practical. We are then obliged to enter into a modification of the system, for the purpose of increasing the size of the dynamos and engine, and reducing their number; and further, in order to reduce the tension in each house to such an amount as can be considered safe for use in private houses. We now arrive at the system of constant current with transformers: such a system is shown in Fig. 6. A is the steam-engine, which is provided with the electrical governor; B the dynamo; C the main conductors in the streets; and D_1, D_2, D_3, &c., the transformers, which are placed in the main conductors; E_1, E_2, E_3, &c., are the house circuits, in which the lamps or other apparatus are arranged in series again. It will be useful to first of all consider the peculiar conditions under which such transformers for constant current are situated, conditions which greatly increase their practical usefulness. A transformer consists of a combination of motor and dynamo, and it is, therefore, apparent that there might be as many modifications in the form of a transformer as we have now in dynamos. The drawing, Fig. 7, is merely to illustrate the principle, and does not indicate the form in which I hope to show to you shortly the transformer in operation. In the drawing the armature of the motor, which is provided with thick wire, and the armature of the dynamo, with coils of thin wire, are entirely separated, and both move in a common magnetic field, which is excited by the current in the primary wire. The shaft of both armatures is situated in bearings which are provided with self-acting oiling arrangements. There are a variety of such arrangements already in use, and in this case the requirements of oil are very small, as there is no one-sided pressure on the bearings, and all the internal electrical forces completely balance themselves in regard to the shaft, so that the friction merely results from the weight of the small armatures. Let us now consider the function of such a transformer.

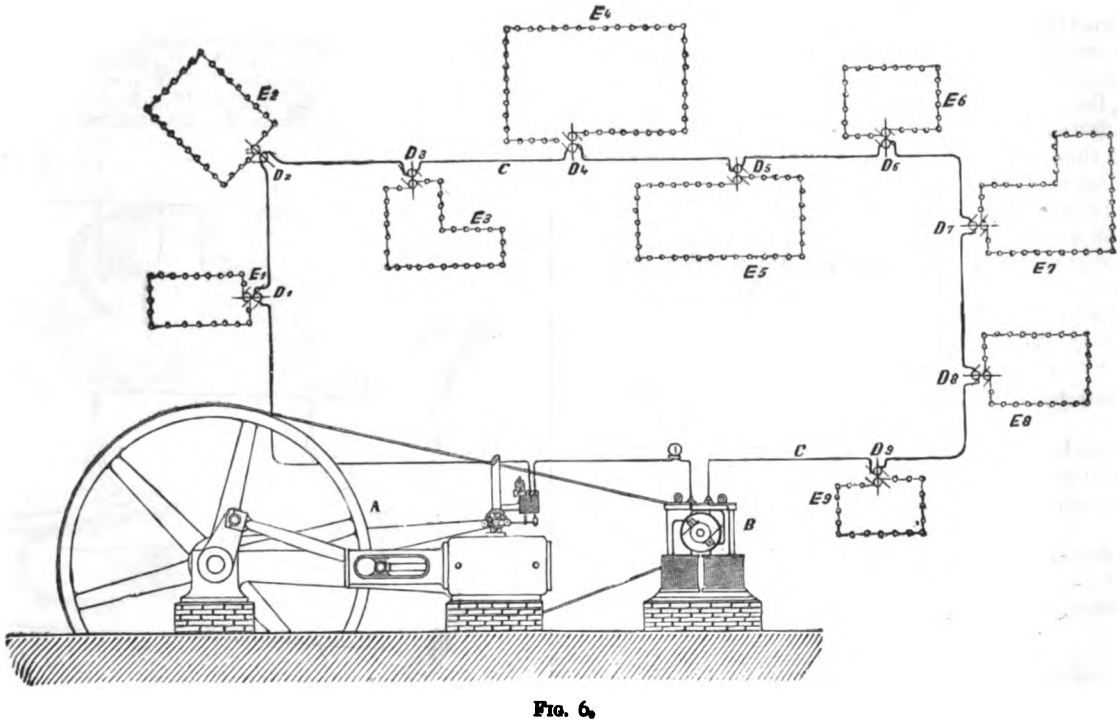

FIG. 6.

The force which must be supplied in order to turn the primary armature under a field of given and constant strength, depends on the current in this armature. This current is kept constant by the means described above. This turning force is resisted by the current in the secondary armature, if we neglect the friction which only absorbs a small part of this force. The current in the secondary armature, which is equivalent to this force, depends on the number of turns of the wire on the

Digitized by Google

secondary armature, in proportion to the number on the primary armature. This proportion being given, the strength of currents are determined which hold each other in equilibrium; or in other words, a constant current in the primary produces a constant current in the secondary circuit. The E.M.F. of the secondary circuit depends on the number of revolutions of the armature, as the field remains constant. Under these circumstances the following will occur:—If, for instance, the primary current is 50 amperes, and the armatures are wound in such a way that a current of 50 amperes in the primary armature is counterbalanced by a current of 10 amperes in the secondary armature, the transformer will assume the speed which produces the 10 amperes in the secondary circuit, because only then the state of equilibrium is obtained. Supposing that with 100 revolutions per minute, and a resistance of 10 ohms in circuit, the E.M.F. is 100 volts, and therefore the current 10 amperes, if now by the addition of lamps the resistance is increased to 20 ohms, the velocity of the transformer must increase also, and now becomes 200 revolutions, in which case the E.M.F. is 200 volts and the current again 10 amperes. The reverse would have taken place if the number of lamps had been reduced. It therefore follows that the transformer in this case has the peculiarity of running at full speed if all the lamps are in use, and of reducing its speed according to the number of lamps which are extinguished. This peculiarity greatly diminishes the wear and tear, and is of considerable practical importance. But there are other circumstances of equal importance which much favour the use of these transformers. In every transformer it is a necessity that the insulation between the primary and the secondary can be well maintained. This is very difficult in a parallel system, in which the high difference of potential, 1,000-2,000 volts, consists everywhere in the circuit, and, therefore, between the brushes of the primary armature. But in the case under consideration, the difference of potential on the commutator of the primary armature is only small. If we, for instance, require a power of 3,000 watts, this difference would only be 60 volts under the conditions assumed above. This makes it perfectly easy to maintain insulation, and, further, to prevent sparks in the commutator. I have already mentioned that the position of the brushes need never be altered in constant-current dynamos; the same is, of course, the case in the transformers. These three peculiarities of the transformer for constant current, viz., the fixed position of the brushes, the small difference of potential in the primary armature, and the change of speed according to the requirements, allow this application of the transformer to be made on which this system is based, because an apparatus which works under so favourable circumstances may be left to itself for weeks, and a periodical, say, monthly, inspection by an attendant is quite sufficient.

I shall now turn to an objection which may be made against this arrangement, and this is that the continuity of the primary circuit is made dependent on the contact of the brushes against the primary collector. Although there is no reason why these brushes should not make contact, as it is easy to devise means which take up the wear of the brushes, I shall suppose that no provision for good contact is made; we can then apply an apparatus which I have used in former years to prevent interruption of the circuit in case of breakage of a lamp. This apparatus consists of an electro-magnet of high resistance, which comes into action if the resistance of the main circuit is unduly increased. The action of this magnet then consists in disengaging a spring or weight which short circuits the primary armature. In this way the faulty transformer is excluded, without in any way disturbing the others. I have already explained that the speed of the transformer will vary according to the number of lamps: this point now requires some further consideration. The secondary armature moves in a constant field, and the E.M.F. is therefore proportional to the speed. The secondary current is constant because the primary is constant. It therefore follows that the number of revolutions of the transformer are a direct measure of the electrical energy which is consumed in the secondary circuit. As a meter the construction of which has never yet received a satisfactory solution in the parallel system, we simply use a registering speed counter attached to the shaft of the transformer. This meter does not register exactly according to the number of lamps which are used, as it measures the total energy consumed, and this is higher in proportion if the number of lamps is small; but this is in accordance with the usual practice, only that in place of an arbitrary scale we have one which corresponds to the expense at the central station. It will hardly be possible to construct a simpler or more rational meter for electrical energy. It is, of course, to be understood that every transformer is provided with a short-circuiting hand-switch, which cuts off the current from the primary armature in case no lights are required in the house.

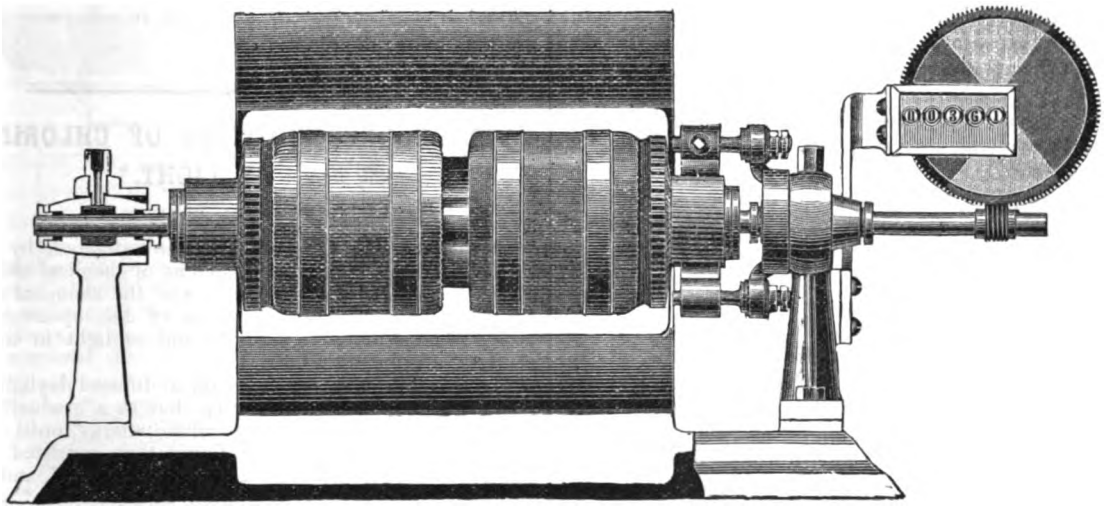

FIG. 7.—Constant-Current Transformer, with Watt Meter attached.

I wish to add here a short remark concerning the alternating current transformer. Those who have advocated the alternating current system will undoubtedly say that the alternating current transformer is more economical than the one proposed here, and they will point to extraordinary results of efficiency which have been obtained by mathematicians; but in spite of these results, the commercial efficiency of these transformers is not any higher than could be expected. In fact, there is no reason why there should be any large difference in favour of the alternating current. The internal resistance is smaller in this kind of transformer, but there is against this the loss due to rapid change of magnetism in the iron. Supposing even that with full load there is a slight difference in favour of the alternating current, the probability is that with half the load the advantage will be on the side of the continuous constant current transformer, arranged in the manner which I have described, as against the alternating transformer in a parallel system.

Digitized by Google

I now turn to the consideration of the secondary circuit. In speaking of the simple-series system I have mentioned 10 amperes as the standard current; but in the transformer system we can use any current in the secondary which answers our purposes. If we have to deal with the lighting of private houses, in which lamps of 8 to 10 candle-power are required, we can use 5 amperes in the secondary, and we can then produce these lights with considerable efficiency, which it is well known is not possible with lamps of 100 volts placed in parallel. For large buildings 10-ampere lamps would be used, and we can then place arc lamps in series with them. In order to obtain a steady light in arc lamps, it is better to supply them with constant current than to put them into a circuit of constant potential. Furthermore, we have to waste considerable energy in resistance in the latter case. I need hardly mention that motors can be placed in the secondary circuit. There are many cases in which the use of accumulators is very desirable for lighting purposes. Probably we shall see charging stations for accumulators for the purpose of propelling street cars sooner or later established in large cities. Now, for charging accumulators it is just constant current that we require and not constant potential; in the latter case we require special arrangements to obtain a constant charging current. The placing of accumulators in the secondary circuit is likely to be the only method which will prove to be practical. It has often been tried to charge these accumulators by means of a high-tension circuit in order to obtain a low tension in the discharging circuit, but the very large damp surfaces of the cells makes it impossible to maintain the degree of insulation required for high-tension currents, and insulation is *conditio sine quâ non* in every system of distribution. A system in which accumulators are placed directly in a high-tension circuit is not only wasteful as far as a current goes, but it contains an element of danger, leaving out the other technical difficulties connected with such a system.

After considering all the various parts of the system, the constructing of a central station plant is easily understood. I shall suppose we have to deal with a plant of 9,000 20 candle-power lamps, or a corresponding number of electrical devices requiring the same amount of energy. The central station contains seven dynamos of 2,000 volts and 50 amperes each, of which one is a reserve dynamo, and each one is driven by a separate steam engine. The whole district is divided into six separate groups, which form independent circuits. In each group 1,500 lamps may be in use simultaneously, and for the sake of simplicity I shall suppose that all transformers are of equal size, namely, each for 50 lamps: we then have 30 transformers in each circuit. If all the lamps are in use, all the engines, dynamos, and transformers have automatically assumed their full speed. In the same measure in which lamps are extinguished in the single house circuits, the corresponding transformers will reduce their speed and react on the engine in the central station. If the consumption of light or power is reduced to a minimum, all the steam-engines will have assumed a crawling motion, which they maintain until the consumption is raised again. All we have to attend to is the management of the plant, to keep steam, oil the bearings, and an occasional inspection of the transformer, which may be done by the same attendant who notes the consumption of energy in each house. Comparing this with the management of a station on the parallel arrangement, with a multiple number of conductors, the great simplicity is very apparent. In the latter case the approximation to constant potential is only obtained by the more careful attention at the central station for the purpose of regulating the supply of energy through each feeder, and the success is constantly dependent on the care which is bestowed to this regulation, besides the attention which has to be given to properly load each dynamo.

If, now, we sum up the advantages of a system of constant current, we can consider these to be mainly as follows:—(1) The possibility of lighting at long distances, and therefore the placing of central stations outside large centres. (2) The economy in regulating the speed of the motive power according to the requirements. (3) The small amount of attendance which is required at the central station. (4) The cheapness of conductors in the streets and houses. (5) The avoiding of fire by overheating of wires. (6) The greatest efficiency of the lamp. To these we have to add all the other advantages to which I have alluded in my Paper.

I have abstained from making any comparison with the alternating-current system, except when I spoke of the transformer itself, but I feel convinced that a system using continuous currents, and having the advantages of the alternating transformer system, must ultimately prove the superior of the two. The use of alternating currents is certainly open to very serious objections, such as the great difficulty of maintaining insulation in cables for high-tension alternating currents, and the great expense of cables suitable for this purpose; the greater danger which is peculiar to alternating currents, even of comparatively low tension; the smaller efficiency of the dynamo and of motors, as well as arc lamps, and the impossibility of charging accumulators—all these are objections which are strongly against the use of alternating currents. I think the alternating current will repeat its history in the development of electric lighting. We have once before seen the alternating current in prominence in connection with the Jablochkoff candle—which, however, has made way for the arc lamp, in spite of the greater complications of the latter. I have no doubt that the alternating-current transformer will again be replaced by a continuous-current transformer. The progress of electrical science gives us the means to carry out constructions which in former years would have been considered as impracticable. The system of distribution by constant current presented far more difficulties to be overcome than have presented themselves to the system of constant potential, when first shown. But I hope that the explanation which I have given in this Paper will induce electricians to consider more clearly all the advantages which are offered by such a system, and that it will pave the way to its more general introduction.

RATE OF DECOMPOSITION OF CHLORINE WATER BY LIGHT.*

BY DR. G. GORE, F.R.S.

In this research the author has investigated, by means of the voltaic balance, the kind and amount of chemical change, the rate at which decomposition proceeds, and the chemical composition of the products formed at all stages of decomposition of chlorine water, when exposed to daylight and sunlight in colourless glass vessels during many weeks.

The chlorine water, by exposure to diffused daylight, was decomposed with moderate uniformity, but at a gradually diminishing rate, as shown by the losses of voltaic energy, until no further loss of such energy occurred; the liquid then consisted of an aqueous solution of hydrochloric acid, hypochlorous acid, and chloric acid. By further exposure of the liquid to daylight and sunlight during several weeks, peroxide of hydrogen was formed, and the amount of hydrochloric acid and of voltaic energy very slowly increased until that of the latter became about equal to that of dilute hydrochloric acid of equivalent strength to the whole of the chlorine present. All the other chief properties of the final liquid agreed with those of a mixture of dilute hydrochloric acid and peroxide of hydrogen. Still further exposure to strong sunlight caused no further change in chemical composition, amount of voltaic energy, or other property of the liquid.

This research shows distinctly that the decomposition of chlorine water by light may be divided into two essentially different parts or periods of chemical change, and that the kinds of chemical change occurring during these two periods are largely different. During the first period a very great and gradual *loss* of voltaic energy occurs, attended by formation of hydrochloric, hypochlorous, and chloric acids. During the second period, a moderate and very slow *increase* of voltaic energy takes place, accompanied by decomposition of the hypochlorous and chloric acids, a further formation of hydrochloric acid, and the production of peroxide of hydrogen. Under the influence of prolonged sunlight, the whole of the oxygen of the hypochlorous and chloric acids united with water to form peroxide of hydrogen, and the peroxide then combined with the whole of the hydrochloric acid to form a definite "solution compound" represented by the formula $2HCl, H^2O^2$.

The chemical composition of the products of the change at the ends of the first and second periods were ascertained by means of the voltaic balance and ordinary chemical analysis. During the first period forty consecutive measurements of the voltaic energy

* Abstract read before the Royal Society, June 20, 1889.

Digitized by Google

at stated intervals of time were made, and the energy diminished from about 1,219 millions to 2·9 millions; and during the second period eight such measurements were made, and the energy increased to 9·3 millions. A curve is given showing the rate of loss of energy during the first period.

It is interesting to observe that suitably decomposed chlorine water, or probably in its stead a mixture of $6HClO + HClO + HClO^3$ in a proper proportion of water, has the property of absorbing energy by exposure to light, very much like that possessed by the green leaves of plants.

THE PAGET ALTERNATE-CURRENT TRANSFORMER.*

In order to overcome the difficulty of unequal efficiencies at different loads, Dr. Leonard Paget has recently designed a type of transformer which adapts itself to conditions existing in the

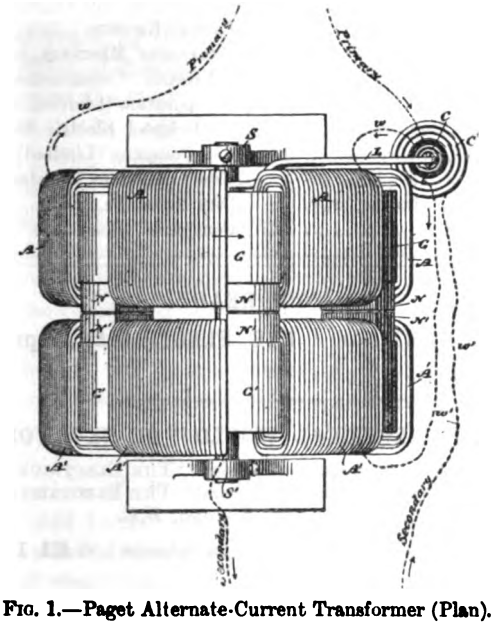

FIG. 1.—Paget Alternate-Current Transformer (Plan).

secondary circuit—that is to say, a transformer which causes the amount of energy utilised in the primary circuit to bear a fixed proportion to the amount of energy required in the secondary circuit in which the lamps are situated, and he accomplishes his object by varying the magnetic circuit in accordance with the load on the

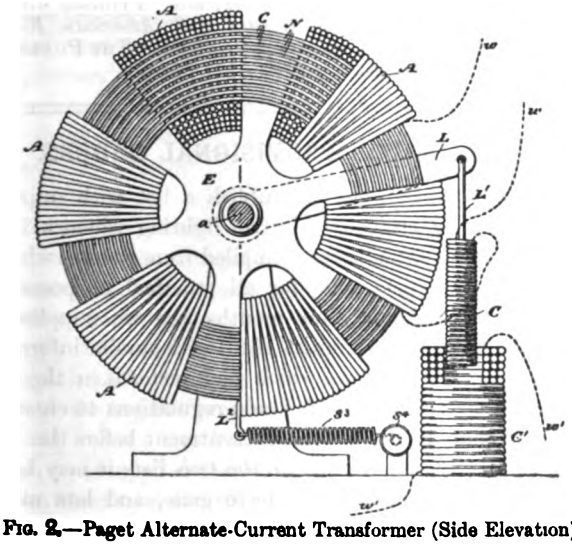

FIG. 2.—Paget Alternate-Current Transformer (Side Elevation).

converter. The accompanying engravings (Figs. 1 and 2) show one form of this new type of converter, Fig. 1 being a plan view showing the circuit connections of the primary and secondary circuits, and Fig. 2 being a side elevation.

As will be seen, the converter is mounted upon two standards, S S′, by means of an iron shaft. Mounted upon the shaft are two iron spiders, which carry a pair of converter coils, A A′, the former, A, constituting a set of primary coils wound in series about the laminated cores G, and made of long, thin strips of iron having projecting teeth, N N′, which constitute the poles of the respective coils, and between which teeth are wound in series on each core the coils A A′. The arrangement is such that when the coils are wound in position the projecting teeth N N fill the space between the coils on one side and N′ N′ between those on the other side. The secondary coils A′ A′ are rigidly fixed upon the axis by a set screw, which passes through the hub, while the primary coils A A are free to rotate upon the axis *a*, and have a lever, L, connected to the hub for producing the rotation. This lever L has connected to its free end a solenoid, C, located directly in the primary circuit and in series with the coils A, as shown. An additional solenoid, C′, is located in the secondary circuit and surrounds the first-named solenoid. The spiral spring, s^3, attached by the lever L^2 to the rotary primary coils, and by an adjusting screw, s^4, to a fixed standard, is designed to regulate the relative location of the cores of the movable and fixed coils under varying conditions.

With this construction the operation of the converter will become evident. Suppose, for instance, that the screw s^4 is so adjusted that the spring s^3 will hold the coils A in the least effective position when a minimum number of lamps are located in the secondary circuit $w' w'$; then, as the lamps are connected in circuit in the usual manner, the influence of the cores upon each other, together with the additional influence of the solenoids C and C′ upon each other in their respective circuits, will cause the coils A to be rotated in the direction of the arrow shown in Fig. 1. This rotation will continue as lamps are cut in to the circuit until a maximum number is reached for the adjustment of the spring s^3, at which time the poles N N′ will lie directly opposite to each other, as shown in Fig. 1, and the multiple magnetic circuits through the twelve adjacent poles of the primary and secondary coils will assume a position of maximum efficiency. The regulation for intermediate positions, as required by varying numbers of lamps in the secondary circuit, is at once obvious, the magnetic circuits varying in accordance with the regulation indicated.

With the construction and principle explained above it is claimed that the efficiency of the transformer is uniformly high for all loads.

* From the *Electrical World*.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-day) FRIDAY, December 6th.

PHYSICAL SOCIETY.

5 p.m. Ordinary Meeting. Papers to be read:—"The Electrification of a Steam Jet," by SHELFORD BIDWELL, F.R.S.; "Notes on Geometrical Optics," by Prof. S. P. THOMPSON, D.Sc.; "On the Behaviour of Steel under Mechanical Stress," by C. H. CARAS-WILSON; "On a Carbon Point in a Blake Telephone Transmitter," by F. B. HAWES.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Students' Meeting. Paper to be read, "Electric Traction." By A. E. CHILDS, Stud.Inst.C.E.

MONDAY, December 9th.

LONDON INSTITUTION.

Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"The Electrician" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

Trade Advertisements *intended for the current issue must be handed in not later than First Post on Thursday morning.*

Small Prepaid Advertisements *(for Rates see page xv.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"The Electrician" Printing and Publishing Company (Limited) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "The Electrician" Electrical Trades' Directory and Handbook. *The Directory was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

THE RACE FOR PROVISIONAL ORDERS.

We are this week able to publish a list with important details relating to projected electric lighting schemes in provincial and metropolitan areas, compiled from sources which we believe to be authentic, and, for all practical purposes, sufficiently accurate. About four months ago we supplied our readers (*The Electrician*, August 16th) with similar information with regard to the schemes which had just taken the initial step required by the Board of Trade regulations to entitle the promoters to share in the general presentment before the Parliament of 1890. By comparison of the two lists it may be seen how far the original applicants have gone, and how many of them have dropped out of the running altogether. From the names of the remaining companies it may be gathered also what are their probable prospects of surviving the test of a Board of Trade examination and the final ordeal of a Parliamentary discussion. Further, the amount of competition on the part of the Local Authorities may be estimated from the particulars given in this week's list, which, in these and many other respects, afford material for a very curious and instructive study.

Digitized by Google

To make the situation clearer, it may be well to state once more what are the conditions under which all these various applications for Provisional Orders have been made. First, it was required of intending applicants that the Local Authorities of the towns affected should be notified not later than July 1st; and it was the acceptances of this preliminary condition that we published in August last. The total number of notices was 474. Our comments on the general character of many of these projects at the time seem to have been borne out by what has followed, for we find, after making due allowance for the fact that in many instances several notices are covered by one Provisional Order, certainly not more than 50 per cent. of them have taken the trouble to testify to their sincerity by going a step further. Between July 1st and the end of November a breathing-time was allowed by the Board of Trade, for the applicants, on the one hand, to estimate their individual chances, and for the Authorities, on the other, to safeguard the local interests. In this interval full advertisements had to be made in the local papers and in the *London Gazette*, giving public notice and description of the powers to be applied for; and a copy of these advertisements, accompanied by a map of the district concerned, had to be lodged with the Board of Trade not later than Saturday last. Down to this point our list is completed, and the total number of applications is now shown to be reduced to 179. Three weeks later a formal memorial, signed by the applicants representing the companies or the Local Authorities, with a draft of the Provisional Order applied for, must be in the hands of the Board.

Before the 21st inst., the date on which this third stage will be reached, many difficulties may arise, and the list may be thinned still further; but not materially, we should imagine, as it is probable that those who have gone so far have had plenty of time to consider whether or not they will make the final plunge. This last will be decided in some cases by the action of the Local Authorities, who have almost everywhere adopted an attitude towards the applicants neither friendly nor ingenuous. To frighten off the intruders they have started applications of their own—some fifty in number—and then, when the enemy was out of sight, have tranquilly dropped all further proceedings. In a few instances this ruse has not succeeded, and we are curiously watching to see which of the competitors will stay in the race for another fortnight. In the majority of instances where local opposition is serious, the town gas supply is owned by the Corporation whose anxiety to protect the town property from injurious competition is at least intelligible, and perhaps excusable. Not so where the avowed or ostensible ground of hostility is the creation of fresh monopolies. It is strange that such a misconception should still survive, but the language we see reported at numerous meetings of the local magnates proves that they have yet to learn that the Electric Lighting Act sanctions no monopolies, and that if they come into existence it will be through the neglect or ignorance of the townspeople themselves.

Quite a large number of towns, however, not owning gasworks, have applied for powers to supply electric light either for the streets or for indoor purposes. Some of these seem to be impelled by disputes with local gas companies; and it is possible there may be no other serious motive than to bring them to their knees. But the larger proportion are, so far as our information goes, actuated by the desire to see the electric light made generally useful, and the not unnatural ambition of undertaking the task on their own account, creating in this way a valuable business for the convenience and profit of the inhabitants. It is, no doubt, a grave responsibility for them, and we heartily wish them well through with it. To us, and to the electrical trades generally, it can matter very little who may order the work so long as it is done. That it may be done well is, of course, a great desideratum, for wherever it is done badly discredit to that extent will fall on the electric light. But in the long-run there is as much likelihood of the undertakings being carried out successfully under local auspices as under the direction of a company with inadequate capital and little experience, samples of which are still to be found in our list of applicants to-day. The demand for electrical plant and for electrical experts will be enormously increased in any case; and the genuine residue of undertakings which are certain to go forward after all deductions are made afford a sure prospect of development in electrical industry such as ought to satisfy its most enthusiastic friends.

We have left ourselves no space to comment on the metropolitan notices, which, however, are given with the fulness to which their importance entitles them. But we invite special attention to two supplementary lists of considerable interest—the one relating to notices in respect to electric traction, the other summarising the number of notices served by each of the applicant companies for electric lighting powers. It will be seen that the whole of the 129 notices, exclusive of those served by Local Authorities, come from 49 companies. One group of companies alone appropriates 53 applications; 15 others emanate from one single company, while the remaining 61 are distributed among 36 companies. The electric traction notices speak for themselves: although not very numerous, they are far in excess of any previous year's experience, and the widely-separated localities for which powers are sought indicate that this application of electrical engineering also is making converts in all parts of the country.

ELECTRIC LIGHTING NOTICES.

The following is a complete list of the intended applications for Provisional Orders which have been advertised in the *London Gazette*:—

THE METROPOLIS.

The Metropolitan Electric Supply Company (Limited), of Winchester House, Old Broad-street, notify their intention of applying for a Provisional Order under the Electric Lighting Acts, 1882 and 1888, authorising them to produce, store, and supply electricity for public and private purposes, as defined by these Acts, in the City of London and its liberties, and in the parishes of Paddington, St. John, Hampstead, St. Pancras, St. Mary, Lambeth; St. Mary, Islington; St. James and St. John, Clerkenwell; St. Luke, Middlesex; and St. Mary, Battersea, and so much of the parishes of Clapham, Streatham, Wandsworth, and Putney as is included in the district of the Wandsworth District Board of Works. The Order will contain clauses authorising the Company to construct, &c., on lands belonging to or held on lease by them within the area of supply such central and other stations and works for the generation, &c., of electricity as may from time to time be necessary for supplying electric current, together with all necessary or convenient buildings, engines, &c.; to lay down, maintain, and alter electric lines, &c., for the supply and distribution of electricity and electric currents above or beneath the roads, &c.; empowering them to manufacture, purchase, hire, and supply meters, lamps, appliances, machinery, &c.; to enter into contracts with Local Authorities, companies, and persons in reference to easements and to the supply of electricity and the works required therefor; to empower the Company to make and levy charges for the supply of electricity, and to define and limit the prices to be charged.

The London Electric Supply Corporation (Limited), of 3, Adelphi-terrace, Strand, will apply for a Provisional Order to authorise them to produce, store, supply, and sell electricity, electric current, and other like agency for public and private purposes within the area constituting the City of London and its liberties. The Order will contain clauses empowering the Company to acquire, construct, and use, and from time to time to sell and otherwise dispose of machinery, plant, and apparatus for the production, storage, regulation, measurement, distribution, and supply of electricity. The works proposed to be constructed, used, and maintained are described generally as follows: A central station, or central stations, at which electricity will be generated or collected, and a system of distributing stations and mains by which electricity will be conveyed and distributed from the central station or stations throughout the area of supply. By other clauses in the Order, the Company will ask for authority to acquire,

Digitized by Google

maintain, &c., and to take up, sell, and otherwise dispose of, electric and other mains, storage and other batteries, accumulators, and other apparatus "for transmitting, storing, measuring, regulating, and distributing electricity for lighting and other purposes, public and private, or for converting the same into power, heat, or otherwise, and any pipes, conduits, or other channels of water supply for feed or condensing purposes, or otherwise to be used for the purposes of, or in connection with, the works and lines to be erected, used, or maintained under the Order, beneath or above the streets, &c., in the area of supply." Power will be asked for to make arrangements with Local Authorities and other bodies to rescind and renew contracts for breaking up or otherwise interfering with the streets, and for the supply of electricity; to levy, make, and recover rates, and to authorise the Company and their *employés* to enter upon lands, buildings, or other premises, and to examine any machinery, &c., supplied by the Company, or used in connection with their lines or works. The Company will also apply for a Provisional Order granting them similar powers for supplying electric lighting in St. Pancras, Islington, Shoreditch, Paddington, Bethnal Green, St. Luke, Middlesex; St. George-in-the-East, Mile End, Hampstead, Hammersmith, Fulham, Whitechapel, Hackney, Limehouse, Poplar, Lambeth, Camberwell, and St. George-the-Martyr, Southwark; Wandsworth, Woolwich, Plumstead, Lewisham, West Ham, and East Ham.

The HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED) will apply for nine Orders, authorising them to produce and supply electricity for public and private purposes,—1, in the City of London; 2, in the parish of Islington and the district of the Hornsey Local Board; 3, in the parishes of Fulham and Hammersmith; 4, in the parish of St. Pancras; 5, in the parish of Lambeth; 6, in the district of the Wandsworth Board of Works; 7, in the parish of Paddington; 8, in the districts of the Acton and the Ealing Local Boards; and 9, in Hampstead, Finchley, Hendon, and Willesden, with powers to acquire lands and to construct works within the various areas of supply mentioned.

Application will also be made to the Board of Trade for Provisional Orders to authorise the LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE, LIMITED (or a Company to be formed on their behalf, called the City of London Electric Supply Company, Limited), to produce, store, and supply electricity for public and private purposes, in the whole of the City of London and its liberties, and with powers to acquire lands, to construct works, and to manufacture and supply lamps, meters, and fittings.

Messrs. A. AND S. GATTI will apply for a Provisional Order to supply electricity for public and private purposes in a portion of the parish of St. Martin-in-the-Fields, and in a portion of the area of the Strand District Board of Works. They also notify their intention of applying to Parliament for leave to bring in two Bills to produce and supply electricity for public and private purposes, 1, within the parishes comprised within the Strand District Board of Works; and, 2, within the Parish of St. Martin-in-the-Fields; to acquire land, &c., and patent rights, and licences for using inventions, &c., relative to the production, &c., of electricity, and to manufacture and supply meters, lamps, &c.

The ELECTRIC CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED), of Worcester House, Walbrook, will apply for a Provisional Order to produce, store, supply, sell, and distribute electricity for public and private purposes in certain parts of the districts within the jurisdiction of the Lambeth Vestry, the Vestry of Camberwell, the Lewisham District Board of Works, the Beckenham Local Board, and the Croydon Corporation.

The SOUTH OF ENGLAND HOUSE-TO-HOUSE ELECTRICITY COMPANY, of 15, St. Helen's-place, E.C., propose to apply for an Order to produce, store, sell, and supply electricity for public and private purposes at Richmond, Mortlake, and Barnes.

The MAXIM-WESTON ELECTRIC COMPANY (LIMITED) will apply for a Provisional Order to produce, store, and supply electricity in Ealing, and for that purpose to construct "a central station, at which electricity will be generated from direct-current dynamos, and also by the alternate currents at high tension, to be converted by transformers where necessary, supply electric energy direct to the mains. Electric energy will also be supplied to storage stations where necessary."

Three Provisional Orders will be applied for by the BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED) to produce, store, and supply electricity, electrical energy and power, 1, within the City of London; 2, within the parishes of Hampstead, St. Leonard, Shoreditch; St. Pancras, St. James and St. John, Clerkenwell; St. Luke, Old-street, St. Marylebone, St. Mary, Islington; and St. Matthew, Bethnal Green; and, 3, within Hammersmith and Fulham; to acquire land, &c.; to erect all necessary stations, &c., and to authorise the Company to manufacture, hire, sell, and let all necessary machines, lamps, accumulators, meters, fittings, &c., required.

Provisional Orders, containing similar powers, will be applied for by the St. James and Pall Mall Electric Light Company (Limited), for the parish of St. James, Westminster; by Messrs. Renshaw, King, and Co., and by the City of Westminster Electrical Syndicate (Limited), for the united parishes of St. Margaret and St. John, Westminster; by the Westminster Electric Supply Corporation (Limited), for parts of the parishes of Paddington and St. Marylebone; by the Chelsea Electricity Supply Company for the parish of St. George, Hanover-square; by the Kensington and Knightsbridge Electric Lighting Company (Limited), for that part of the united parishes of St. Margaret and St. John, Westminster, which is not included in the Kensington and Knightsbridge Electric Lighting Order, 1889, and for the parishes of Paddington, St. Marylebone, and St. George, Hanover-square; and by the Electricity Supply Corporation (Limited), who will apply for two Orders, one for the parish of Paddington, and the other for the St. Giles District Board of Works, and the District of the Strand Board of Works.

PROVINCES.

Town, &c.	Name of Applicants.
Aberdare.....	Western House-to-House Electricity Company.
Aberdeen	Messrs. Norman and Son.
	Scottish House-to-House Electricity Company.
Accrington	The Corporation.
Airdrie	The Corporation.
Ashton-under-Lyne	Municipal Electric Light and Power Corporation (or Company to be formed).
Ayr	The Corporation.
	Messrs. Norman and Son.
Bacup	The Corporation.
Barnsley	The Corporation.
	National Electric Supply Company.

ELECTRIC TRACTION NOTICES.

The following is a list of Companies proposing to obtain powers to employ electric traction :—

THE METROPOLIS.

Applicant.	Powers sought.
Central London Railway (Company to be formed).	To make and maintain underground railways or subways from Bayswater to the City, and to use electricity or other mechanical power (other than steam locomotives).
City & North of London Railway (Company to be formed).	To make and maintain underground railways or subways from the City of London to Islington ; and to use as motive power electricity, or any other mechanical power (other than steam locomotives).
City of London and Southwark Subway Co. (Limited).	To extend existing line from Stockwell to Clapham, and to use electricity or any other motive power (not being steam locomotive engines).
Kensington and Paddington (Subway) Railway (Company to be formed).	To make and maintain a (subway) railway from South Kensington and Paddington, and to use electricity as motive power.
Lea Bridge, Leyton, and Walthamstow Tramways Company.	To construct, maintain, work, and use a tramway, and to employ animal power and any electrical or other mechanical power, except steam locomotives.
London Central (Subway) Railway (Company to be formed).	To make and maintain a (subway) railway from Tottenham-court-road to Shepherd's Bush Common, and to use electricity as motive power.
London Tramways Company (Limited).	To construct and maintain a tramway across Westminster-bridge, and to use animal or mechanical (other than steam locomotive) power for moving carriages.
New Cross, Lewisham, Brockley, Forest Hill, and District Tramways (Company to be formed).	To use animal power, or any electrical or other mechanical power.
North and South London Subway Railway.	To construct an underground railway from Camden Town to the Elephant and Castle at Newington Butts, and to use electricity, pneumatic, cable, or other suitable power.
North London Suburban Tramways Company, and North London Tramways Company.	Use of steam or other mechanical power in working.
North Metropolitan Tramways Company.	To use on the tramways of the Company electrical or other mechanical power, fixed or movable (other than steam), in substitution of or in addition to animal power ; and to hold and acquire patents and other rights, or licence to use patent rights, in relation to any such mechanical power.

THE PROVINCES.

Aldershot and Farnborough (Hants) Tramways Extension.	To construct and maintain tramways, and to use steam, electricity, or other mechanical or horse-power for haulage of the cars.
Bradford (Yorks.) Corporation.	To lay down, construct, and maintain street tramways, and to authorise and empower the use of steam or other mechanical power, or electricity or cable haulage.
Drypool and Marfleet Steam Tramways Co. (Ltd.) and Hull Street Tramways Co. (Ltd.).	To authorise the Drypool Company to run over and use the tramways of the Hull Company by animal power, and steam, electrical, mechanical, or other power.
Folkestone, Sandgate, and Hythe Tramways Company.	To use animal, mechanical, or electrical power of any description.
Huddersfield Corporation	To construct or purchase tramways to be worked by electrical or mechanical power.
Lynton Railway Co.....	To employ electricity or any like agency, either in addition to, or in substitution for, steam power.
National Rifle Association.	To construct, maintain, and work a tramway on Bisley Common (Surrey), and to use animal, steam, electric, or other power.
Penzance and Newlyn (Cornwall) Tramways (Company to be formed).	To construct, maintain, and work tramways, and to employ cable or other mechanical or electric power.
Plymouth Tramways Company.	To use steam or any mechanical power, or electricity or the cable system.
Pontypridd (Glamorgan) Tramways (Company to be formed).	To make and maintain tramways, and to use animal or mechanical (other than steam) power for moving carriages or trucks.
Warboys and Paddock Drove (Hunts.) Tramway (Company to be formed).	To construct, maintain, use, and work a tramway, and to employ animal, electricity, steam, or other mechanical or motive power.
Wellingborough and District (Northants and Bucks) Tramroads Company (Limited).	To form, lay down, maintain, and use tramroads, and to use steam, electricity (by the overhead system or otherwise), or other mechanical power for moving carriages or trucks thereon, and to provide (if thought fit) that such powers shall not be revocable by the Board of Trade or otherwise.
West Hull Tramways Company.	To purchase part of the tramways of the Hull Street Tramways Company, and to use animal power, and steam, electrical, mechanical, or other power.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"Electrical Engineering in America."*

BY G. L. ADDENBROOKE, ASSOCIATE.

The last eighteen months or two years in America have been much more characterised by commercial and industrial progress with already existing types of plant and apparatus than by a number of new inventions. Inventive ability seems to have been more concentrated on improving and elaborating already existing inventions than on the evolution of new forms and ideas.

The leading types of machines and apparatus are all well known to you, and have been so fully described and illustrated that to enter into a minute account of them now would only be to traverse old ground. I therefore propose to devote myself this evening to central station, construction, and internal work, and the application of electricity to tramway and other industrial purposes. Finally, I propose to make a few remarks on the tone, policy, and aims of American electrical engineers, and those commercially interested with them in advancing the application of electricity.

My visit to America was not quite of the ordinary character, as I came through on my way from Australia, and consequently had to traverse the whole breadth of the continent before reaching the better known towns on the Eastern Coast. I was thus able to make a general, if rapid, survey of what is going on in the far West and in towns remote from the manufacturing and engineering centres, as well as in New York and some of the larger cities.

Overhead Work.

Throughout the continent, from shore to shore, the main thing that forces itself on the observer is the prevalence of arc lighting. Hardly any what we should call moderate-sized village outside the oil region appears to be without its arc lamps. Arc lamps, when used for public lighting, are usually fixed on poles from 20ft. to 40ft. high, according to the caprice of the parties interested in their erection ; or they are slung from the corners of intersecting streets, in which case they usually hang low down ; or the tower system is adopted. When posts are used, they are of rough pine, never painted, often out of the straight, and warped or bent. If the lamps are fixed, iron spikes are usually driven at intervals on each side of the pole, starting about 8ft. from the ground, and forming a sort of ladder by which to reach the lamp. During my whole journey from San Francisco to New York, I can hardly recollect seeing one ship-shape, neat, and smart-looking post, whether for carrying arc lamps or for any other electrical purpose. Everything has a temporary and expedient look about it which is very offensive to English eyes. Creosoting does not seem to be practised, and the only protection applied to the poles which I saw anywhere, consisted of boards fixed round the base and reaching about six feet high ; but this protection was, I think, only applied to large poles carrying circuits or telephone wires. The lamps themselves are always entirely without ornamentation, and are usually very roughly fixed on the poles. If the globes are not clear glass they are usually only lightly frosted, so that the light glares in one's eyes in all its nakedness. When the lamps are hung over the centre of intersecting streets, four wires are brought down from the corners of the neighbouring houses, the lamp hangs from the centre, and is lowered and raised by a pulley and cord. The wires from which the lamp hangs, the cord, and the leads all festoon about in accordance with the chapter of accidents, and look, as we should think, both slipshod and untidy. The only relief to this state of things is afforded by the towers. These towers are usually erected at the intersection of streets, with the four legs at the four angles of the pavement. They are constructed of exceedingly light ironwork. Tapering gracefully upwards to a great height, they are, at any rate, neat and not

* Paper read before the Institution of Electrical Engineers, November 28, 1889.

Digitized by Google

uninteresting-looking objects in themselves, and certainly form very definite landmarks. Three or four arc lamps hung round the top of one of these towers shed a sufficient light over a great area where the houses are not high. With this method of distribution a 20-light machine can be employed to great effect, especially as in country towns and villages where these towers are chiefly employed the object is rather to make darkness generally visible, if I may so express it, than to provide bright illumination in well-defined places. By using the tower method one's eyes are not dazzled by the brightness of the light, which is so much the case with lamps at a low level. In my own case, I used sometimes at night to get quite an irritated feeling when walking about, if at all tired, from the incessant glaring in one's eyes of naked arc lamps, and the impossibility of finding rest anywhere. I mentioned this effect to two or three Americans, but they did not seem to notice it.

Important, however, as the public lighting is, in the large towns it occupies a comparatively inconspicuous place in comparison with the number of lights used for illuminating stores, saloons, hotels, restaurants, and all sorts of public buildings. Arc lamps are so lavishly used in these places, both inside and out, that the principal streets are often literally a blaze of light. There were, as far as I could ascertain, about 2,000 arc lamps in nightly use in San Francisco, 3,000 in Chicago, and I understood that 3,500 were shut down in New York while I was there, owing to the accidents which had taken place, and of which so many accounts have been published. The majority of the arc lamps used outside are fixed by means of light iron rods projecting from the buildings, though some, of course, are hung. The circuits feeding lamps hung either inside or outside of a building either run direct from the nearest poles on each side of it, thus making an angle over and across the pavement which is very unsightly, or a sort of barrel-shaped glass insulator is used. This insulator has a hole through the centre and a groove round the middle of the outside. The wire coming in one direction is passed through the centre of the insulator, turned back on itself, and made off; the wire in the other direction is passed round the outside, and also made off on itself; the two ends of the loop are then carried to the lamp, through which the circuit is completed. Nearly all the wire I saw was insulated with "underwriters' insulation." Where lamps are used internally, this is often carried through wooden window-frames and such other like places without any further protection or care. Once inside, the wire is carried along ceilings and walls quite exposed, but separated about 3in. by small wooden cleats. Sometimes instead of cleats small white porcelain insulators are used. As far as I could learn, it is the invariable custom for all companies to run, fix up, and entirely look after the lamps they operate. The customer simply pays a rent for the use of the lighted lamp of so much a week, month, or year, as the case may be, and has no further trouble of any sort. The rates differ according to the time the lamps are to be in use each night. To see that the lamps burn properly, linemen promenade the streets all night, and are supposed to see every lamp on their circuits at certain intervals.

The circuits themselves are almost invariably carried on poles erected along the edge of the kerbstones. A fair estimate of the average height of these posts is, I think, about 30ft.; of course some are much more, and many less. Long wooden cross-arms are fixed near the top of the poles, carrying from two to six, and even eight, insulators on each arm. These arms are not so strong as we should make them for the purpose. Owing to the length of the arms, and to their not being very securely fixed to the poles, the weight of the circuits often pulls them out of the horizontal. To see a warped and bent pole, set crookedly in the ground, and with the arms at various angles with each other, and the wires on it all hanging in different curves, seems about as dismal and woe-begone a piece of engineering as can well be imagined. I must make some exception, however, in the case of the Thomson-Houston Company, in New York, who at any rate, had got light iron stays attached to the poles and arms, at an angle so as to give more support to the arms, and keep them in their places. The insulators are supported on the arms by wooden pegs, which have a screw-thread cut on the part that projects. On this one of the ordinary green glass insulators is screwed. Green glass insulators are used for every purpose in America, whether for electric light, telegraphs, or telephones. They are very cheap, and answer the purpose well. Still, the effect of green glass insulators on arms painted a dull red, fixed on bare poles from which the bark has just been stripped, is not æsthetic. The majority of the poles for circuits have no steps provided for ascending them. On the frequent occasions when it is necessary to go up to the top to make alterations or add new circuits, the linemen use climbing-irons. The tearing of the wood by the spikes of these climbing-irons gives the poles a jagged and frayed-out appearance from top to bottom. One could fancy they lead to the habitation of some immense squirrel.

The Americans nearly always use solid wire for running their circuits, covered, as I have mentioned already, with underwriters' insulation. Little trouble is taken to keep the various circuits on one pole in regulation with each other, as long as they do not touch. Indeed, the whole construction of the poles and arms is so flimsy that no great strain could be put on the wires. The poles themselves are fixed at short intervals, often not more than 30 yards apart, and seldom above 60. The circuits are rather hung up on the poles than run, in the sense an English lineman attaches to the word. Separate suspenders I never saw used, except for telephone cables. For alternating incandescent circuits of 1,000 volts several separate cables of small size are also used, instead of running a large one with suspenders, as has been the custom here.

What I have just said about short spans for electric light work also applies to telephone and telegraphic work: the spans used in this work are generally also short. In the latter case, since the wires are light, they are run pretty taut without putting much strain on the arms, so that there is not much sag. Wires run in this way are of course not so liable to sway about as long spans are in high winds, and make intermittent contact or get overlapped. Further, the wires, being run along the streets, are protected from high winds in a great measure, and are not particularly exposed to them, as our over-house work is. This method of erection, therefore, rough as it is, and notwithstanding the enormous number of wires which are often suspended from one pole, gives an immunity from contacts and accidents that an English engineer at first can hardly understand and appreciate.

For leading in wires into houses, or for putting on extra wires on a pole—in fact, for general purposes of the sort—a block of wood is used, the lower end of which is cut off at an acute angle, the upper being cut away and turned down, and a screw-thread cut on it to carry an insulator. When the face of the angle is fixed against the side of a house or a pole, and a spike or screw put through it, the insulator projects somewhat, and forms a support for making off the wire. The whole thing is of the cheapest description, but, nevertheless, seems to answer its purpose. Wires are led in from the outside with much less care than is generally used in England; and this applies also to telephone and telegraph work. It often puzzled me how they worked at all after they had been put up a few months. But the fact that the climate is much drier, and fine rain not so frequent as here, has no doubt a great deal to do with it. In the case of arc light circuits entering and coming out of houses, and worked in series—as they always are—it is, of course, a material point that although the difference of potential between the circuit and the earth may be 3,000 volts, yet the difference between the outgoing and incoming wire is only some 50 volts; so that the tendency of the current to break across the leads is really small. Again, the chance of the current going to earth on dry ceilings and walls is, when one comes to look into it, not great. Thus, notwithstanding the rough character of most American work, and the poor insulation of the wires, in this class of work there is a greater freedom from faults and a higher margin of safety than one would at first imagine. The only place where the margin of safety is really low is where the wires enter buildings.

I have now, I think, gone over all the main points in arc lighting construction work. Construction work for alternating currents is generally carried out on much the same lines as for arc-lighting; the only difference is that in the latter case converters are stuck against the outside of buildings instead of arc lamps, which, of course, are in parallel instead of in series. A rough hole is knocked through the brickwork just under the place where the converter is fixed, for the secondary leads, which are slipped through a couple of rubber tubes and carried inside. But little attempt is usually made to execute this part of the work in what we should call a neat or workmanlike manner.

Let us now make a *resumé* of this branch of the subject. There are in America now, I believe, more than a quarter of a million arc lamps in constant use. In the large towns these arc lamps are fed by machines equal to keeping going 50 or 60 lamps each. Outside a central station, supposing it to be for 1,000 lights, we shall find tall and untidy-looking poles 30 or 40ft. high. At the top these poles will have four or five cross-arms, each carrying six or eight insulators. These poles will be continued along the neighbouring streets at intervals of 30 to 60 yards, according to circumstances. Every here and there a circuit will leave the rest for the side of a neighbouring house, supply one or more lamps, being run in the latter case along the face of the houses, and then return again at the next pole. Or a circuit may jump across the street, supply a lamp or two, and then return again to the nearest pole on the side it first started from. Here and there one or two circuits will leave the main line of poles altogether, and turn up a side street: in this case the poles in the side streets are generally smaller. It is surprising the length some of the arc circuits extend in this way—not unfrequently over a dozen miles. As all the machines in a station are usually of the same size, and are run at the same speed, when the circuit is long the number of lamps fed off a nominal 60-light machine may perhaps have to be reduced to 45 to allow for the resistance of the leads. As you are aware, some of these arc machines are now used on power circuits in the daytime, which forms a very welcome source of extra revenue. I trust I have not wearied you by a too minute descrip-

Digitized by Google

tion of this, a not very interesting part of electrical engineering in America; but I was anxious to convey as clearly as I could on what a remarkably simple and crude basis almost the whole fabric of American electrical engineering in this particular at present rests. For I think I am not overstating facts in saying that at least nine-tenths of all the electrical work in America—putting aside isolated plants—is carried out, as far as the construction work is concerned, in the manner I have described. In all this portion of the work I saw next to nothing which showed particular ingenuity, skill, or brilliancy of idea. Simple and crude means were everywhere used to effect in a rough and crude manner the end desired. In the means employed there is little to excite either admiration or interest. The interest lies in the fact that in such a simple and elementary manner so much has been done.

(To be continued.)

A NEW VIEW OF TELEPHONE INDUCTION.*

BY JOHN J. CARBY.

One of the most peculiar developments connected with the introduction of the telephone was the presence of remarkable sounds which were heard when the telephone line was of any considerable length. Sometimes it sounded as though myriads of birds flew twittering by; again, sounds like the rustling of leaves and the croaking of frogs could plainly be heard; at other times the noise resembled the hissing of steam and the boiling of water. Even a display of Aurora Borealis causes powerful currents in the telephone. At one time, I think it was in 1882, during the prevalence of sun spots and after the appearance of a comet, the auroral current became so strong on a line from Boston to Brockton as to operate a miniature arc light which I improvised out of a pair of lead pencil carbons and connected into the line. Some of these disturbances have been more or less satisfactorily accounted for by assuming differences of potential at the two ends of the line, by the sudden heating or cooling of the line, and by the passage of electrified bodies of air or clouds. Another very curious effect was observed when the first two telephone wires were run parallel to each other on the same cross-arm for the distance of even a few miles; it was found that, although the insulation of the lines was high, a conversation carried on over one wire could plainly be heard on its neighbour. This overhearing is commonly called "cross-talk." As the number of telephone wires increased, and their bunching together in cables became necessary, it was found that in addition to the cross-talk there was another element of trouble added, which was due to the electrostatic effect of the cable, and caused the voice to be transmitted in an indistinct and muffled manner. This evil exists to such an extent that where cables are used the speaking limit is soon reached. While a study of the strange noises heard in the telephone might be of interest, I shall in this Paper limit myself to the consideration of cross-talk and to the action which takes place when wires are bunched in cables. In the simple case of inductive cross-talk first cited, in which two telephone wires are strung parallel on the same cross-arm, the presence of cross-talk is said to be due to dynamic or current induction; that is, if a current commences to flow in one of the wires from north to south, it will at that instant cause an induced current to flow in the other wire in the opposite direction, from south to north. As the telephone current is constantly changing its direction and strength, this explanation seems to apply, and is the one given in the text-books. This is the kind of induction referred to in the law of Lenz, and applies to induction coils and to parallel wires when the current is of sufficient strength. I shall speak of this hereafter as electro-magnetic induction. To-night I shall describe some experiments which seem to prove that the induction between telephone wires is due to electrostatic rather than to electro-magnetic action.

I will first show a case of electrostatic induction between telephone wires in which there is a neutral point at the centre of the secondary wire, at which point there is no induction, while at the ends marked inductive effects are noticeable.†

In Fig. 1, E F and C D are two well-insulated parallel telephone wires, each 200ft. long, and placed one-eighth of an inch apart. E F is open at one end and connected to ground at the other through a Blake transmitter, L, in the ordinary manner. In front of the Blake transmitter I place a vibrating tuning-fork, which acts on the transmitter in the same manner as the voice, and which produces impulses in the line E F of the same strength as voice currents. At the centre of the line C D we have the telephone Y, and at the extreme ends the telephones X and Z. With the tuning-fork at L in operation, tones are heard at X and Z, but the middle telephone Y is silent. A study of the changes of potential produced in the wire E F by the transmitter will give us an explanation of this phenomenon. As is well known, the telephone current is an alternating one, and the potential of the line E F varies constantly and is changed from positive to negative many times per second. The wire E F being open at E would be at the same potential throughout. It is assumed that at a given instant the height of potential at F would be represented by the dotted line F H; then the potential at E would be represented by the dotted line E G, and the total

FIG. 1.

charge on E F would be represented by the rectangle E G H F. We will assume that this charge is of the minus sign. The existence of this charge on E F pre-supposes the presence of a charge of opposite sign on C D, which would be represented by the rectangle A C D B. Now, suppose the potential on E F becomes zero, owing to the operation of the transmitter, then the whole charge on E F gets to earth at the grounded end of E F, but the charge on C D has two paths to earth, one at C and the other at D. This results in two currents, as shown by the arrows, one flowing to earth through the telephone X and producing sound at X, and the other flowing to earth through the telephone Z and producing sound at Z. No current flows through the telephone Y, and consequently no sound

FIG. 2.

is produced therein. Again, changing the potential of E F causes a corresponding set of currents, but in opposite directions to those first described, meeting in the centre and producing no sound in the centre telephone, but causing the end telephones to give out sounds the same as in the first instance. Inasmuch as the line E F is opened at one end, and therefore has almost an infinite resistance, it is clear that this phenomenon is purely an electrostatic one. In this and the succeeding experiments I have not attempted to give the exact shape of the induced charge, as it would unnecessarily complicate the subject and would not in any way affect the result. As a matter of fact, the dotted line A B should slope off from the centre toward the ends. With the line E F grounded through an

FIG. 3.

ordinary subscriber's line and instrument, the effect is the same as when the line is open, and the neutral point is still found. This is because the telephone current, even when flowing in a closed circuit, is so weak that it is not capable of producing a magnetic field of sufficient strength to affect the neighbouring wire, or the magnetic effect is so small that it is obliterated by the movement of the static charge. For convenience, in some of the succeeding experiments the disturbing wire will be shown open at one end.

If there is no current flowing at the neutral point, opening the wire at that point should have no effect on the telephones located at the end. In Fig. 2, A B is the disturbing wire with the transmitter L arranged as before; K is a key located at the neutral

* Read before the New York Electric Club, November, 1889.

† In explaining an experiment of Mr. Culley before the Society of Telegraph Engineers in 1875, Mr. Preece pointed out that in a certain telegraph line subjected to induction from a neighbouring telegraph line, there was a neutral point. I can find, however, no reference to this in Mr. Preece's book on "The Telephone," and its practical application to telephone induction seems to have been lost sight of.

Digitized by Google

point of C D. With the transmitter L in operation no change is produced in the tones heard at the telephones X and Y by opening and closing the key K. If this induction were electro-magnetic, opening the line C D would prevent current from flowing in any part of the circuit. In Fig. 3 we have another proof of the electrostatic nature of telephone induction. A B is the usual disturbing wire with its transmitter L. C D is the secondary wire with the telephones X and Y located at the ends, as in the previous experiment. By means of the key K the telephone X may be cut in and out of the circuit. With the key open the usual tones are heard at X and Y. Now, if the induced current flowing in the circuit C D is due to electro-magnetic induction, upon short-circuiting the telephone X and thereby reducing the resistance of the circuit C D, the strength of the induced current should be increased and the tone at the telephone Y should be correspondingly louder. But this is not the case, as on closing the key the sound at Y, instead of being increased, entirely disappears. This is because the charge on the wire C D finds an easy path to earth through the key, and such a small portion of the charge goes to earth through the telephone Y, that no audible effect is produced therein.

Fig. 4 shows the disturbing wire A B arranged as before, but the secondary wire, instead of being put to earth at both ends, has its circuit completed by a second wire placed outside of the field of A B. With this arrangement neutral points are found at T and T^1, while the usual disturbances are heard at telephones R and R^1, located at the ends. In this case a movement of the static charge takes place in the metallic circuit, causing at one moment a set of currents starting from T^1 in both directions through the end telephones and meeting at T, and at the next instant the reverse takes place.

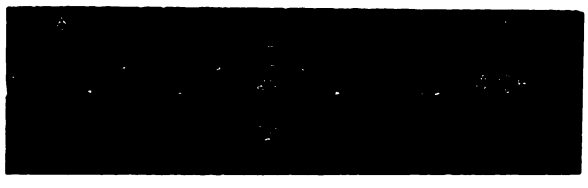

Fig. 4.

I will now show some of the effects of electro-magnetic induction, at the same time suppressing electrostatic induction. In Fig. 5, A B is the disturbing wire as before, but grounded through a short thick wire at A. Instead of placing the tuning-fork in front of the transmitter L and acting on it through the air, producing delicate currents like voice currents, an automatic circuit breaker and five cells of Leclanché battery were connected in the primary circuit of the transmitter, thus producing in the line A B alternating currents of great strength. The secondary wire containing the telephones X, Y and Z is of the same length and at the same distance from the disturbing wire, as in the previous experiments. With the circuit breaker at L in operation, loud musical tones are heard at X, Y and Z, and the tone is the same in all three telephones, the neutral point in this case having disappeared. This is a true case of electro-magnetic induction, because short-circuiting

Fig. 5.

the telephone Y increases the sound in the remaining telephones and leaving the short circuit on Y, and short-circuiting the telephone X still further increases the sound at Z. This latter experiment furnishes a most striking contrast to the result obtained in Fig. 3, where by short-circuiting the telephone X, the sound was completely removed from the telephone at the other end of the line. Another proof that this is electro-magnetic induction is found in the fact that if the line be opened at Y, the sound disappears from all the telephones. If the line A B were opened at A, the potential along the line would be constant, and the charge which A B would take would be represented by the rectangle A G H D, but when the line is grounded at A, through a low resistance, there is, of course, a fall of potential along A B ; the principal drop, however, occurring in the secondary coil of the transmitter L, the line B E representing the height of potential at the terminal of the coil, and the electrostatic effect which the line A B would have is represented by the triangle A E B. This triangle, although exaggerated in the diagram, is still much smaller than the rectangle A G H D, and explains the absence of electrostatic induction between the wires, while the powerful current generated in L, and the comparatively low resistance through which it has to flow, accounts fully for the electro-magnetic effects observed. I have made a large number of laboratory experiments and observations on actual telephone lines, all of which point strongly to the conclusion that electro-magnetic induction does not exist in telephone lines outside of the telephone and transmitter. This view of the subject applied to the theory of transpositions of metallic circuits and to the action of wires in cables gives the only satisfactory explanation of observed phenomena.

Now, we come to the important question : Can this electrostatic induction be prevented ? In answer to this, it may be said that the cross-talk due to electrostatic induction can be eliminated by properly-constructed metallic circuits. But there still remains the muffling effect referred to in the first part of this Paper. This is sometimes called " electrostatic retardation, " and comes in wherever two telephone conductors are run close to each other for any great distance. Where telephone wires are strung upon poles, and are at a distance of a foot or more from each other, this action is very small, but where they are bunched together in cables—a hundred or more within a 2in. pipe—it is very great. It is a curious fact, however, that the amount of this trouble, other things being equal, depends on the character of the insulating medium or dielectric, as it is called, but is independent of its specific insulation resistance, the induction being less when air is used as an insulator than with any other substance among the materials adopted in practice. Dry cotton, paper, and silk rank next to air in this respect, but when gutta-percha or any of the rubber compounds are used, the induction is much greater than with the other materials mentioned. This peculiar property of an insulator, *i.e.*, the facility with which it allows induction to take place through it, is called its " specific inductive capacity." In the present state of the art, then, the only way to overcome electrostatic retardation, after having an insulator or dielectric of the lowest specific inductive capacity, is to increase the distance between telephone conductors. It is evident that in underground systems this distance can never be great. In all of our large city underground systems the space which is allowed for each wire is ·125 of an inch.

This putting wires underground in cities is the only bar to a universal system of telephony, and if direct air lines were built, New York and Chicago would be placed within speaking distance of each other at once. To place telephone wires underground, and maintain the same efficiency as in overhead lines, would require an insulation on each wire of over two feet in thickness, and instead of getting 50 pairs of wires into a 3in. pipe, as at present, a tunnel occupying half the street would be required for one cable alone. When we consider that a telephone office of even moderate size would require about a hundred such gigantic cables, it is seen how almost hopeless the case becomes.

Most engineers think that this difficulty is inherent in the problem, and that the electrostatic action can only be overcome by separating the wires as already stated. In view of the recent researches tending to give us a deeper knowledge of the nature of electricity which have been conducted by Hertz and others, I think there is reason to hope that some other way out of the difficulty may be found. You are all, no doubt, familiar with those celebrated experiments wherein electrical undulations of many million times per second were produced, and, although they were transmitted along a conductor with the velocity of light, yet they followed each other with such rapidity that nodal points were produced, the location of which determined the length of the waves. These waves have been produced in various ways, and by means of large prisms of pitch and by metallic mirrors they have been refracted, focused, and reflected. In fact, they have been found to obey much the same laws as light waves. I think it must follow from these experiments, that our disturbing wire, A B, is throwing off, laterally, waves of great length, and that these waves, impinging upon the adjacent wire C D, produce the various inductive effects observed. Now, if by some means these waves could be deflected from their course and prevented from falling on the wire C D, it follows that there would be no disturbance whatever produced therein. We know that if these waves were of the same length as light waves, this action could be prevented by the interposition of a properly-shaped lens of glass, or by a mirror ; or if they were of the length used in Hertz's experiments, a lens of pitch or a metallic mirror would have the same result. Now, although the telephone waves are of great length, it seems possible that by interposing a properly-shaped dielectric or combination of dielectrics, an interference or refraction might be produced which would have the desired result.

This electrostatic problem is one of the most important, and, until within a year or two, the least studied, and is at present the least understood of all the various difficulties with which we are confronted, and the reward which awaits its proper solution is greater than that which fell to the lot of the inventor of the telephone itself.

THE GILBERT CLUB.

On Thursday afternoon last the inaugural meeting of the Gilbert Club took place at the rooms of the Society of Arts. The chair was taken by Sir William Thomson, and among those present were Sir Frederick J. Bramwell, Dr. B. W. Richardson, Prof. D. E. Hughes, Prof. John Perry, Prof. George Forbes, Mr. Latimer Clark, Mr. G. J. Symons, Dr. Atkinson, Mr. H. Trueman Wood, Dr. Laver, Mr. J. Lane, Prof. Silvanus P. Thompson, D.Sc. (Hon. Sec.), and Mr. Conrad W. Cooke (Hon. Sec.).

Prof. SILVANUS THOMPSON explained the objects of the club. What that club proposed to do was to commemorate the tercentenary of William Gilbert, and to do honour to him by reproducing in English the great work which began the science of electricity. Besides the immediate literature of Gilbert himself there was a very large amount of contemporary literature of very great interest to those who studied the early history of the sciences of electricity and magnetism; and it seemed that the Gilbert Club might possibly, in the event of its first work being successful, hereafter reproduce some of those other books. At the same time, it seemed undesirable to commit the club to anything more than the carrying out of the two specific objects, viz., to subscribe the English translation of Gilbert's work, "De Magnete," and form the nucleus of an organisation hereafter for the tercentenary celebration. He concluded by moving the first resolution constituting the Club, which was as follows:—"That the 87 persons who have already signified their acceptance of the invitation to be enrolled among the members of the Gilbert Club be hereby constituted members, together with such others of those who, having already received notice of invitation, shall signify their acceptance thereof before the close of 1889."

Dr. B. W. RICHARDSON seconded the resolution, and said that he did so with special pleasure, inasmuch as he had been an old student of Gilbert, had written a memoir of him, and had lectured on him several times.

The resolution having been carried unanimously,

Mr. CONRAD W. COOKE moved the following:—

"That the objects of the Gilbert Club be as follows:—(1) To produce and issue an English translation of 'De Magnete' in the manner of the folio edition of 1600. (2) To arrange hereafter for the tercentenary celebration of the publication of 'De Magnete' in the year 1900. (3) To promote inquiries into the personal history, life, works, and writings of Dr. Gilbert. (4) To have power after the completion of the English edition of 'De Magnete' to undertake the reproduction of other early works on electricity and magnetism, provided at such date a majority of the members of the Club so desire."

Prof. FORBES seconded the resolution, which was carried unanimously.

After some discussion it was resolved, "That all proposals for membership be referred for the present to the Council, hereafter to be chosen, for selection, up to the number of 200 in all."

Prof. HUGHES proposed, and Sir FREDERICK BRAMWELL seconded the election of Sir William Thomson as president of the club, and the resolution was unanimously carried.

The following vice-presidents were then elected:—Mr. Jonathan Hutchinson (President of the Royal College of Surgeons), Dr. B. W. Richardson, Lord Rayleigh, Dr. Henry Laver, of Colchester, Prof. Reinold, and Prof. Hughes. The following gentlemen were elected to serve on the committee:—Mr. Lant Carpenter, Prof. Ferguson, Sir Philip Magnus, Prof. Rücker, Prof. Foster, and Prof. Forbes. Mr. Latimer Clark was elected treasurer, and Mr. Conrad W. Cooke, Mr. Raphael Meldola, and Prof. Silvanus P. Thompson, hon. secs. The meeting terminated with votes of thanks to the Society of Arts and the Chairman.

THE CENTRAL LONDON ELECTRIC RAILWAY.

The following are some additional particulars with regard to the Subway Railway Scheme, to which we alluded in our last issue:—

Among the many schemes deposited at the Houses of Parliament on the 30th ultimo in which electricity plays so large a part is one for an electric railway, starting from Queen's-road, Bayswater, under Oxford-street, Holborn, Newgate-street, Cheapside, and King William-street, to Arthur-street West, where it is proposed to connect it with the nearly finished City and Southwark Subway, extending to Stockwell.

Although by no means a new idea as regards route, it is novel in its method of attaining its end, inasmuch as the plan sought to be adopted obviates the necessity of in any way interfering, either during construction or afterwards, with the surface of the streets—this, in the view of the promoters, being likely to minimise the great opposition which has hitherto been brought to bear upon previous schemes dealing with these thoroughfares. It is proposed to employ two separate tunnels lined with iron, each of 11ft. in diameter, widening out materially at the different sites proposed for stations. They will be bored in the solid clay, driven under a steel shield (the plan adopted in the subway under the Thames at London Bridge), which it is held will successfully guard against the possibility of any settlements of foundations of property; and, being below the gravel, any risk of danger from water. All the soil excavated it is proposed to bring to the surface at the station sites, which sites will also be used for lowering all the ironwork necessary for the construction of the tunnel. It is not proposed to have any shafts along the route, as the passage of the trains through the tunnel, it is anticipated, will be sufficient to cause a thorough circulation of the air; and as electricity alone will be used both as a motive force for the train and for lighting purposes, the ordinary causes of foul air in underground railways will not exist. The speed proposed to be obtained is 14 to 15 miles an hour. One of the most important of the City stations suggested by the plans is nearly opposite the General Post Office, where a block of buildings now stands facing the entire length of Cheapside; another is to be in the immediate vicinity of the Royal Exchange. At all the stations hydraulic lifts are to be provided (in addition to the ordinary stairways) of very large capacity, and similar in construction and working to those in use at the Mersey Tunnel. The engineers responsible for the scheme are Sir John Fowler, Mr. Benjamin Baker, and Mr. J. H. Greathead, the last-named gentleman having now practically brought to an issue the City and Southwark Subway. Messrs. Ashurst, Morris, Crisp, and Co. are the solicitors for the promoters, whilst Messrs. Sherwood and Co. will have charge of the Bill through Parliament in the ensuing Session.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 23, 1889.

The Overhead Wire Agitation.—As might have been expected, the recent agitation in this city on the subject of overhead wires has been followed by sympathetic agitation all over the country. Thus, at Cincinnati, the Board of Public Works has ordered the electric light wires throughout the city to be buried, and the order now awaits the approval of the Council. In Philadelphia the City Council have taken up the matter, and have elaborated a time schedule, giving the local companies a certain time for the removal of the wires in certain districts, so that at the end of a series of years the whole city should be free from overhead wires. As in most ordinances of the kind, the time allowed is all too short, and it may be taken for granted that the wires will not be underground when the end of the period fixed arrives. In Boston, affairs have taken a somewhat different shape. It being proposed to deal there with the question of overhead wires, the local electric club invited the Mayor of the city, the Fire Commissioners, and other officials to dinner, and then, having dined and wined them, treated them to an interesting discussion on the Municipal regulation and control of electric wires and wiring. A great many views were expressed on the subject by electrical men present, and there can be no doubt that, even if the Mayor were not given a unanimous opinion, he is much better informed as to what electricians think and believe, and is the more likely to act with discretion than if he had simply acted on the spur of the moment and under the impulse of fiery newspaper writing. It has been proposed to establish in Boston some kind of Conduit Commission, and it seems likely that a Board of Supervision will be established. At a meeting of the Common Council just held in that city, the Mayor has been instructed to petition the Legislature for an Act giving the city further control of the erection and maintenance of all electric light wires, with authority to remove dead wires, to require satisfactory insulation, and to regulate the voltage of currents of all classes. It will be seen that the action taken by the Boston electricians in seeking to furnish their chief magistrate with sensible ideas on the subject was an excellent one. It is to be hoped that if a Commission be appointed for Boston such as has been proposed, it will contain men who are informed on the subject and able to grapple with

Digitized by Google

the problems involved. Some idea of the insincerity of the recent clamour in the Press of New York City against electric wires is shown by the manner in which some of the papers which were strongest in their denunciations of the overhead wires have been warmest in their approval of the ordinance granted by the Mayor and Board of Aldermen for the construction of a cable road on Broadway. It is well known to those who have studied the subject that the operation of cable roads has been attended everywhere with a large number of deaths from accidents. The vital statistics of such cities as San Francisco and Chicago reveal deaths from cable railway accidents out of all proportion to the number of deaths from electricity that have occurred in New York City, where, as everybody knows, the conditions have been such as to invite rather than forbid fatalities. Yet, with the long list of accidents elsewhere staring them in the face, the newspapers calmly turn round, and approve the adoption of cable railways for one of the most important and most crowded thoroughfares in New York City. I would not be understood as running cable railways down. They are a great boon in every way, and have done much to educate the public mind up to the idea of traction by motive power other than horses; but when one sees such inconsistency as this on the part of those who have made the lives of New York electricians miserable for the last month or two, it is but timely and proper to utter an energetic protest.

The Ries Method of Securing Continuous from Alternating Currents.—The subject of securing continuous from alternating currents is attracting a great deal of interest and attention in this country at the present time, and the discussion promises to lead on to important results. With regard to the scheme recently proposed by Mr. Nikola Tesla for obtaining such currents without the use of mechanical commutators, Mr. E. E. Ries now comes forward to make some claims on his own behalf. The idea of Mr. Tesla's invention is one in which a continuous opposing or counter-electromotive force or electromagnetic force, or an equivalent active opposing resistance or tendency, is set up against one or both sets of current waves for the purpose of separating and directing them into their respective channels. Such methods, however, Mr. Ries has found to be open to objection so far as their employment for continuous-current work is concerned, for the reason, first, that the currents flowing in the two branches are intermittent or pulsating instead of continuous; and, second, that because of such intermittent flow the reactions set up within the circuit containing the generators of the counter current, if the battery or the magnet or the converter coils proposed are constantly in circuit, will interfere seriously with the satisfactory operation of the system, and be wasteful of energy. This last difficulty Mr. Ries meets and overcomes by the employment of a pulsatory or intermittent counter force, corresponding in periodicity to and by preference derived from the current which it is desired to commutate. In the system which Mr. Ries has developed, however, the various difficulties referred to are preferably avoided by dividing the positive and negative waves from two separate sources of alternating current, the waves of like sign from one source filling in the intervals between the similar waves or impulses from the other in such a way as to produce a practically continuous flow of current over both circuits. Such a form of apparatus devised by Mr. Ries consists of an alternating-current dynamo having two armatures, or a single armature provided with two separate sets of coils, so arranged that one armature or set of coils is half a period in advance of the other. In calling attention to his work, Mr. Ries goes on to develop the idea, and to point out that continuous-line currents can similarly be converted into intermittent pulsations or intermittent current without the employment of mechanical commutators.

New Baxter Motor.—A short while since I noticed in this letter the fact that Mr. Wm. Baxter, jun., was introducing a new type of electric motor, and that he proposed to apply it to street-car propulsion, his idea being to dispense entirely with gearing, placing the motor on the car-axle and driving direct. Mr. Baxter's ideas on the subject have now been further made public, and Mr. Baxter shows his motor applied directly to street-car trucks, or rather the street-car wheels. The motor is located in the back of the car-wheel, covered by a metallic casing, strong enough to hold the entire weight of the car, so that the mechanism is in no way exposed to accidents from shock or collision, and is rendered waterproof. The velocity of the motor is so low that there is no difficulty in keeping the brushes and commutator in perfect order, and Mr. Baxter flatters himself that he is likely to derive great advantage from the whole arrangement. According to Mr. Baxter, the power required to run a car of his new type, dispensing with the gearing, and with an average load of 20 passengers, bears to the power required to run a geared car the proportion of 14,513 to 24,263; or reducing to percentages, the system requires but 60 per cent. of the power used in the geared systems to do the same work.

The Form and Efficiency of Incandescent Lamps.—The Paper read before the American Institute of Electrical Engineers this week on "The Form and Efficiency of Incandescent Lamps," by Mr. Charles J. Reed, embraces a number of points which, though possibly not absolutely new, are well worthy of being pointed out, as many fall into the error which Mr. Reed seeks to correct. If, according to Mr. Reed, we neglect the small amount of heat lost by conduction from the ends of the filament to the conducting wires, and assume that the space surrounding the filament is a perfect vacuum, then the entire energy of the current will be expended in radiation. But this rate of radiation depends only on the elevation of the temperature of the filament above that of the surrounding space and the specific radiating power of the surface at that temperature. He then develops the fact that the square of the current is proportional to the cube of the temperature of the filament for all lamps with constant temperature, and that this relation is independent of the potential, of the length and resistance of the filament, and independent of the candle-power. The final conclusion of Mr. Reed is that the illuminating efficiency of a lamp at any given temperature is constant, and independent of the potential, length, radius, resistance, current, and candle-power of the filament. This means that the energy required to produce a given candle-power will be proportional to the candle-power, and will be the same whether it is expended in driving a large current through a short thick filament or a small current through a long slender filament, provided the temperature or state of incandescence is the same, and provided no heat is lost by conduction from the terminal wires. In the discussion which followed, Prof. Nichols, of Cornell University, corroborated from his own experiments the conclusions reached by the author, and pointed out that comparative experiments in this field were exceedingly difficult, on account of the great difficulty of obtaining lamps in which the vacuum is alike in all. A slight difference in this respect, he showed, would have a very marked influence in the radiating power of the lamp, and hence the temperature reached with a given current.

VIENNA NOTES.

(FROM OUR OWN CORRESPONDENT.)

VIENNA, *December* 2, 1889.

Since October 1st, the trunk line between Vienna and Prague has been in operation, and, as far as traffic is concerned, it has been a decided success. The *average* number of conversations per day has been considerably over 100, counting Sundays and holidays, and the maximum reached has been over 170, whereas on week-days it is generally between 135 and 145. The newspapers use it most extensively, and all the papers in Prague have ordered special tables from the Telephone Company, with telephones arranged on them, so that they can speak, hear, dictate, and write at the same time. Thus, up to midnight, the line is always occupied. As the line is well made, and has very little induction indeed, the service is most satisfactory, and the exchange subscribers in Prague converse with those in Vienna, and *vice versâ*, as easily as in the case of the local service. At present there is only one circuit to Prague. It is a question if with the second circuit, which will have to be added sooner or later, the service will remain as excellent as it is now.

Three circuits are now being run to Budapest from Vienna, and will be ready for public use in a very short time. It will be very interesting to see how far overhearing will disturb the conversation on these lines. To what extent these telephone lines diminish the

Digitized by Google

telegraph revenue is difficult to ascertain, but there can be no doubt that as far as newspaper telegrams are concerned they do so considerably.

The telephonic service for transmitting telegrams from subscribers to the Telegraph Office and *vice versâ* has certainly not suffered so far. In Prague it has increased rapidly since the telephone trunk line was opened. In October, 1888, 3,137 were transmitted from the Telegraph Office to subscribers, and 1,503 from subscribers to the Telegraph Office—total, 4,640. In October, 1889, the figures were respectively 3,595 and 1,945—total, 5,540. This special service is increasing every month in the Telephone Company of Austria's stations. During the first seven months of 1889, 67,116 telegrams were transmitted through their eight exchanges, and the number of their subscribers has now risen to 2,783, with 5,977 kilometres of wire run.

Silicium-bronze wire, 1·25 mm. in diameter, is used in all exchanges in Austria. Many experiments, made by the General Manager of the Telephone Company of Austria, have proved that in using silicium-bronze wire all idea of soldering joints should be given up, and during the last two years no joints have been soldered in the Company's exchanges, with the result that the breakages of wire have decreased to a very large extent. One cannot avoid heating the joint more or less in soldering, and this at once affects the silicium-bronze wire, diminishing its strength by nearly one-half. Instead of soldering, a special joint is made, which gets tighter and tighter the greater the strain, and makes good contact. All experiments now show that the wire never breaks near the joint. This is due to the fact that that part of the wire which is bent to make the joint has practically no strain on it, the wire itself running straight through.

A very pretty and useful tool for telegraph and telephone inspectors and workmen has just been brought out by M. Sedelmaier, of Munich. This tool clears the ends of insulated wire of their insulation, and at the same time scrapes the core.

In electric lighting some activity prevails. The Electricitäts Gesellschaft are building a large Central Station, and Messrs. Siemens and Halske are nearly ready with theirs. The streets are being torn up in all directions, especially in the Mariahilf suburb (the busiest in Vienna), and if the business is at all proportionate to the amount of inconvenience caused, the companies engaged in inaugurating this new departure ought to succeed very well indeed. Evidently the Stock Exchange thinks so, as the Electricitäts Gesellschaft's shares have been run up to a ridiculously high premium. Hitherto, the only large Central Station in good working order has been the splendid one of the Imperial Continental Gas Company, lighting the Opera House and Burg Theatre. The plant and station is large enough to light a large quarter of Vienna, and it seems a pity that the company should rest content with what they have, and do not try to secure their proper share of electric lighting in the city. In Budapest, of course, Messrs. Ganz and Co. reign supreme, so far as electric lighting is concerned, though it is rumoured that the Société d'Installation d'Air Comprimé et de l'Électricité have applied to the Town Council for licence to light a very large part of the town. In Innsbruck Messrs. Ganz and Co. have opened a large station. The power is supplied by the Wurmbach, which has been made to have a fall of 115 metres, giving about 600 horse-power; two turbines of 150 horse-power are used, coupled direct to two dynamos. The primary conductors carry a high-tension current of 2,000 volts to the Central Station, which is about three kilometres outside the town. Transformers are used to convert the high-tension current into one of 100 volts at different places. The mains are overhead outside the town and underground within its boundaries.

Two accidents which recently happened in Temesvar clearly show that the greatest care must be taken with electric light installations. On November 3rd the town was alarmed twice. The first time a report spread that the town-hall was on fire. Though this was happily not the case, yet a fire had broken out in the house of the Chamber of Commerce. The wires in the court of this house became short-circuited, the insulating material melted off, and the wooden cases in which the lines ran caught fire. The fire was extinguished by the fire brigade, the wires being seen to by the engineer of the Brush Company. The second disturbance took place owing to bad contacts, near the cathedral, much in the same manner as the above.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *November* 30, 1889.

The Christiania Telephone Company is now in a fair way of getting better accommodation than it has hitherto had, as the alteration of the new house it has bought is commenced. The telephone hall will be enlarged to about twice its present size, and will occupy almost the whole of the second floor, while the first floor will be used for offices, &c., and on the ground floor will be the telephone exchange for the public. The telephone hall will be remarkably well lighted, and altogether fitted out in the best style. The building will have electric light, and will be heated from a central heating apparatus.

The town of Orebro will join the number of Swedish towns which have adopted electric light for the streets. At a recent meeting the Corporation, after much discussion, decided upon this course.

The telephone between Stockholm and Gothenburg continues to give great satisfaction. In Stockholm you can with ease converse with another person at another telephone *viâ* Gothenburg, which is a distance of about 1,000 kilometres.

The Elektriska Aktiebolaget in Stockholm has several provincial central stations in hand similar to the one the Company installed at Vesteras last year. At Arboga the installation comprises 500, and at Ostersund more than 1,000 incandescent lamps. Also at Helsingborg, Sweden, the electric light will shortly be introduced for street lighting.

CORRESPONDENCE.

THE ELECTRIC TANNING PATENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I send you herewith copy of letter received from my solicitor respecting the action "The British Tanning Company *v.* Groth," which is brought to restrain me from working my patent, No. 742 (1888), for tanning with the aid of electricity, as being an infringement of a patented process for producing a similar result, which process was purchased from the patentees, Messrs. Worms and Bale, by the British Tanning Company last spring. I shall feel obliged if you will take note of this matter in your next issue.—Yours, &c., L. A. GROTH.

3, Tokenhouse-buildings, London, E.C., Dec. 3, 1889.

[COPY.]

Fred. Bradley, 75, Mark-lane, London, 29th Nov., 1889.

L. A. Groth, Esq., 3, Tokenhouse-buildings, E.C.

Dear Sir: British Tanning Company (Limited) *v.* Groth. The motion for injunction herein came on for hearing this morning before his Lordship Mr. Justice Sterling, when he declined to make the order as asked, and ordered the motion to come on for hearing at the trial of the action.—Yours faithfully, (Signed) FRED. BRADLEY.

THE SILVERTOWN STRIKE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As incorrect statements continue to appear in some of the daily newspapers with reference to the strike at the India Rubber, Gutta Percha, and Telegraph Company's Silvertown works, we shall be obliged if you will publish the following facts in your columns:—

In consequence of 380 of our workpeople striking, about 900 others, whose work was dependent on steam power, were thrown out of employment. Of this number, and of the original strikers, many have found work elsewhere.

It has been stated that we have lately taken on a few "calendar hands" only; but the fact is, we are glad to say, that as we have been able to provide steam power, about 350 of our old hands have, within the last few days, returned to their employment in our various workshops. Others have applied, and we will take them on as fast as we can arrange work for them.

The number now in our employment at Silvertown is 795. Our wages list for this week amounts to £1,350, most of which will go to alleviate the distress in the neighbourhood, distress which has been caused by the action of the strikers, and prolonged by the misstatements and misleading promises of the agitators.—Yours, &c., WM. J. TYLER, Secretary.

THE MANUFACTURE OF OZONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your remarks *re* ozone in your issue of November 22nd, I beg to advise you that I have—and have had for some time—the management of an ozone plant, which turns out daily many thousand cubic feet of this powerful and remarkable gas, and which we could easily increase to an almost unlimited quantity. Unfortunately, the inventor is not in town, being indisposed, or I should be able to obtain his permission to give you more particulars.—Yours, &c.,

JOHN C. LAWSON, Manager.

6, Newman's-row, Lincoln's-inn-fields, W.C., Dec. 3, 1889.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

PADDINGTON LIGHTING.—The Vestry of Paddington invite applications for the right to light by electricity the Borough of Paddington on and after Tuesday, December 10th. The specification can be seen at the Vestry Hall, Harrow-road, London, W., on and after Tuesday next. Tenders have to be sent in, addressed to Mr. Frank Dethridge by the 16th. Further particulars are given in our advertisement pages.

VACANT APPOINTMENT. — The Barnet Local Board are about appointing a Lighting Inspector. Letters must be addressed to Mr. H. W. Poole, Clerk, Barnet, on or before Tuesday next. Some particulars will be found in our advertisement columns.

SALES BY AUCTION.—We would remind our readers that Wednesday next is the date fixed for the sale by Messrs. Wheatley Kirk, Price, and Goulty, of the plant, loose tools, and effects of the Victoria Engine Works, Chester (at 11 o'clock prompt).—The same firm will sell by auction on Tuesday, the 17th inst., at the North Bridge Electric Works, New Bank, Halifax, Yorks. (at 10 for 11 o'clock prompt), the modern machine tools, new dynamos, cable instruments, plant, patent rights, patterns, stores, stock, and effects of Luther Hanson and Co., Limited (in liquidation). Further particulars of both sales are given in the advertisements on page iii.

MESSRS. PRICE, TALBOT, AND CO. (LIMITED).—This is the title of a firm being established to take over the concern of Dale and Co., Ludgate-hill, E.C. The new firm will undertake the business of electricians, optical and philosophical instrument makers, &c.

THE NETHAM CHEMICAL COMPANY (LIMITED).—We have received a handy box of specimens from this Company. The three bottles enclosed contains samples of (1) crushed first sal ammoniac; (2) refined chloride of ammonium (large crystals), No. 7; (3) refined chloride of ammonium (small crystals), "R.S.," all for use in batteries.

THE GÜLCHER ELECTRIC LIGHT AND POWER COMPANY. — We have received the new illustrated catalogue of this company, which contains full particulars with regard to the dynamos, arc lamps, switches, and electrical accessories manufactured and sold by them. The Gülcher Company has hitherto been associated with the direct-current low-tension system of distribution, but they are now manufacturing high-tension alternate-current plant. In the "Fricker" alternator, which has a stationary armature, special care has been taken to provide for the easy examination and repairs of the armature coils. The "Battersea" transformer is of a compact description, and its ventilation is very thorough.

MESSRS. ERNEST SCOTT AND CO.—This firm's catalogue just to hand contains particulars relating to their dynamos for lighting, depositing, and plating, motors, arc lamps, and general electrical plant and apparatus. It consists of more than 100 8vo. pages, has a full index, is fully illustrated, and is accompanied with a useful price list and code-word for turbine installations.

MESSRS. DAVIS AND SON (DERBY).—We have received from this firm a circular, descriptive of a cheap ceiling rose, made of porcelain. The fuse is enclosed and attached to cover, and has a 1in. break. The springs are brass, and are attached to the base. These springs hold up the cover, and form the contacts. It is claimed for the rose that it is wholly self-contained, and that the weight of the pendant tends to improve the contact.

THE PLANET ENGINEERING COMPANY.—This Company have just fitted up the extensive new premises of Messrs. John Barker and Co., of Kensington, with the electric light. A reception and ball were held on the premises on Monday last, and the ground and first floors of the building were lighted by 42 "Alpha" arc lamps, and the rooms of floors above were lighted by seven Sunbeam and over 60 small incandescent lamps, the current being supplied from the mains of the Kensington and Knightsbridge Company.

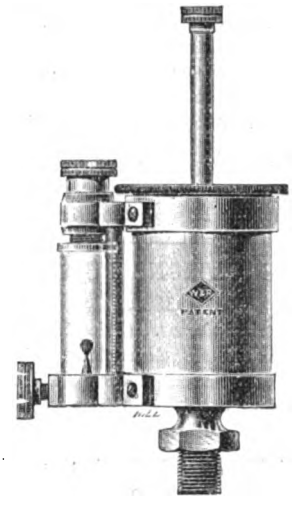
THE TROPICAL AMERICAN TELEPHONE COMPANY (BOSTON).—We are in receipt of a neatly-printed octavo catalogue from this Company, full of practical details for the erection of telephones, bells, &c. The pamphlet, which consists of 50 pages, is full of illustrations, from a call-bell to a multiple switchboard for 3,000 subscribers. This Company owns the patents of Bell and Blake for Central and South America, and the West Indies.

SCIENTIFIC APPLIANCE MANUFACTURING COMPANY (IN LIQUIDATION).—Creditors of this Company are required to send particulars of their claims to Mr. J. A. Hulme, 41, Glen Eldon-road, Streatham, on or before January 15, 1890.

SELF-WINDING AND SYNCHRONISING CLOCK COMPANY (IN LIQUIDATION).—Creditors of this Company must sent in particulars of their claims to Mr. J. D. A. Norris, Suffolk House, Laurence Pountney-hill, Cannon-street, London, E.C., on or before December 28th.

FAIRBURN AND RAWSON'S PATENT SIGHT-FEED LUBRICATOR.

We illustrate herewith the latest form of this well-known lubricator, manufactured by Messrs. Woodhouse and Rawson United (Limited). It is claimed by the patentees that this lubricator possesses all the advantages of other similar lubricators, and that there is no necessity for fixing it to a steam-pipe. It is applicable to any bearing or other working surface. The position of the rod above the cup, as shown, indicates the condition of the supply.



By removing the cover and drawing the piston the supply can be renewed. Regulation is effected by means of an adjustment screw at the lower left side, and any required number of drops can be made to float up through the water contained in the glass tube, from which the oil flows down a metal tube to the stem below. A screw cap above the top bracket allows the tube to be easily filled with water. The lubricator is supplied at a reasonable price, and a large number of them are now in use.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

November 6, 1889.

17,643. C. BROTHERHOOD. Bristol. An improved method by means of electricity of reducing friction in bearings and other parts of machinery.

17,652. J. H. RIDER. Halifax. Improvements in electric arc lamps.

17,675. W. A. HIGGINBOTHAM. Dublin. A new or improved apparatus for governing the electromotive force of dynamo electric machines driven by gas engines and other impulsive engines.

17,694. E. WILSON. London. An electrical Watt meter.

November 7, 1889.

17,754. J. M. SPINK. London. Improvements in conductors of electrical energy.

17,762. F. L. RAWSON and W. WHITE. London. Improvements in electrical switches.

17,763. F. L. RAWSON and W. WHITE. London. Improvements in or applicable to electrical switch-boards and switches.

17,765. H. J. HADDAN. London. Improvements in electro-magnetic dispatch apparatus or portelectrics (J. T. Williams, United States).

17,781. W. WHITE. London. An improvement in electric switches.

November 8, 1889.

17,785. W. SMITH. London. Electric burglar alarm contact-hinge.

17,793. G. J. WEIR and A. WEIR. Glasgow. Improvements in galvanic batteries.

17,819. A. SLATTER and W. RIXON. London. Improvements in switches for making and breaking electric currents.

17,831. J. V. SHERRIN. London. Improvements in electric battery, carbon, and carbon compound elements and their connections.

November 9, 1889.

17,914. W. CLARK. London. Electrically controlled steam steering gear (Sigmund Schuckert and Co., through Wirth and Co., Germany).

November 11, 1889.

17,930. J. H. TUCKER. Birmingham. Improvements in incandescent electric lamps.

17,974. H. H. LAKE. London. Improvements in apparatus for welding by aid of electricity, which improvements are also applicable for other purposes (H. Temp, United States).

Digitized by Google

November 12, 1889.

18,004. R. A. Sloan. Liverpool. Improvements in incandescent electric lamps (G. W. Wilson and C. H. Brown, United States).

18,010. J. A. Timmis. London. Improvements in lamp fittings for electric lighting.

18,018. A. J. Boult. London. Improvements in electro-magnetic brake and traction-increasing system (E. E. Ries and A. H. Henderson, United States).

18,028. E. de Pass. London. Improvements in moulding plates for electric accumulators (La Société Jacquet Frères, France).

18,051. H. H. Lake. London. Improvements in and relating to electric signalling apparatus, chiefly designed for use in hotels and other buildings (F. E. Morgan, United States).

18,067. A. B. Cunningham. London. Improvements in the manufacture of secondary batteries or accumulators.

November 13, 1889.

18,110. J. Farquharson. Acton. Improved winding of armatures of dynamos.

18,112. H. Edmunds (of the Firm of W. T. Glover and Co.). London. Improvements in the metal sheathing of electrical cables.

18,159. C. Weuste. London. Improvements in electric contact apparatus.

SPECIFICATIONS PUBLISHED.

1888.

16,129. Lansard. Electrical alarms. (Price 6d.)

18,233. Taylor. Duplex electric telegraphs. (Price 8d.)

18,525. Wilson. Alternate-current motors. (Price 8d.)

18,589. Huber. Secondary batteries. (Price 8d.)

18,636. Fuller and Fuller. Electrical accumulators. (Price 4d.)

18,659. Siemens Bros. and Co., Limited (Taylor). Electric motors. (Price 8d.)

1889.

1,112. Gwosdeff. Telephony, &c. (Price 6d.)

1,113. Gwosdeff. Telephony. (Price 6d.)

3,556. Firth and Crabtree. Regulating current developed by dynamos. (Price 6d.)

11,705. Englebach and Bright. Preventing loss of surplus electricity generated by dynamos. (Price 8d.)

12,378. Storey. Electric rock drills. (Price 6d.)

12,390. Currie. Electric motors. (Price 8d.)

12,418. Boult (Cobb). Insulating tubing for electric conducting wires. (Price 8d.)

COMPANIES' MEETINGS.

The Electric Construction Corporation (Limited).

An extraordinary general meeting of the Electric Construction Corporation (Limited) was held on Thursday last at the offices, Worcester House, Walbrook, under the presidency of Sir Douglas Fox.

The SECRETARY (Mr. F. Walton) having read the notice convening the meeting,

The CHAIRMAN said: Your Directors are sorry, gentlemen, to have given you the trouble to come here to-day, as we met so recently, but I do not think you will consider the reason of our calling you together unsatisfactory. We have duly applied, as we promised we would, to the Stock Exchange for a quotation of this Company's shares, and you are convened this afternoon for the purpose simply of passing some very formal resolutions to meet the requirements of the Committee of the Stock Exchange. That is the whole business before us to-day, but, at the same time, I think, as we have the opportunity of meeting you, it may be interesting to you to know that since we last met all the purchases of the properties comprising this Corporation have been completed, that the general business of the Company is proceeding in a manner thoroughly satisfactory to your Directors, and that it shows every sign of realising to the full the expectations which we formed in regard to it. Having said that much, I will now proceed with the formal business of the meeting. I move, therefore,

"That the Articles of Association be amended, except as to Article 8 (which is the second in the list), in accordance with the terms of the notice convening this meeting, dated November 19, 1889, as follows:—

(1) "'That Article 8 of the Articles of Association of the Company be amended by inserting after the word "place" in the first line thereof the words "in the United Kingdom."

(2) "'That the following Article be added after Article 8:—8A. "No part of the funds of the Company shall be employed by the Directors of the Company in the purchase of the Company's shares."

(3) "'That Article 19 be amended by inserting after the word "shares" in the second line thereof the words "not fully paid."

(4) "'That Article 25 be amended by adding at the end of the Article the words, "no call shall exceed one-fourth of the nominal amount of a share, and two months at least shall intervene between the time appointed for the payment of one call and that appointed for the payment of the next succeeding call (if any)."

(5) "'That Article 31 be amended by omitting from the seventh, eighth, and ninth lines thereof the words "or regulated by the amount of dividends from time to time to be paid by the Company, or its not divisible profits."

(6) "'That Article 35 be amended by omitting from the fifth line thereof the words "whether fully paid up or not," and inserting in lieu thereof the words "not fully paid up."

(7) "'That Article 88 be amended by omitting the whole of the article, and inserting in lieu thereof the words "The qualification of a Director shall be the holding of shares of the Company of the nominal amount of £1,000. A first Director may act before acquiring his qualification, but shall in any case acquire the same within one month from his appointment, and unless he shall do so he shall be deemed to have agreed to take the said shares from the Company, and the same shall be forthwith allotted to him accordingly."

(8) "'That Article 105 be amended by inserting after the word "shall" in the seventh line thereof the word "not," and by omitting from the seventh line thereof the words "sit at the Board and," and by inserting in the ninth line thereof the words "in which he is," in lieu of the words "notwithstanding his being," and by omitting from the ninth line thereof the word "therein," and by omitting from the tenth and eleventh lines thereof the words "but he shall not be bound to disclose the extent of his interest."

(9) "'That Article 130 be amended by adding at the end of the article the words "other than the shares of the Company."'"

The CHAIRMAN read the various articles in their amended form, and added that the alterations were all of a purely formal character.

Sir DANIEL COOPER seconded the motion, which was put and carried unanimously.

The CHAIRMAN then moved that Article 8A in the notice be amended as follows:—

"No part of the funds of the Company shall be employed by the Directors of the Company in the purchase, or in loans upon the security, of the Company's shares."

Sir HENRY MANCE seconded the proposition, which was also unanimously agreed to.

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.

Digitized by Google

The CHAIRMAN thanked the shareholders for their attendance, and said it would be necessary to call another meeting for the purpose of confirming the resolutions.

The proceedings then terminated.

The Blackpool Electric Tramway Company (Limited).

The annual meeting of the shareholders of this Company was held in the Victoria School Room, Tyldesley-road, on the 23rd ult. Mr. R. Horsfall, J.P., presided.

The SECRETARY (Mr. R. Handley) having read the notice convening the meeting,

The CHAIRMAN, in moving the adoption of the report and balance-sheet declaring a dividend of 7 per cent., trusted that the same would meet with their approval. The property and assets were much the same as the previous year, with the exception that they had invested in the New Zealand Bank a sum of £2,000, which bore interest at the rate of 4½ per cent. They would also find the expenditure side of the balance-sheet in a satisfactory state, running, as it did, item for item with last year. With regard to the receipts, they must congratulate themselves upon the good season which had been experienced in Blackpool, and which had enabled the Directors to make out so good a balance-sheet. No doubt some of the shareholders would be surprised at the proposals they made of dealing with the money. They proposed paying a dividend of 7 per cent., placing to reserve and depreciation fund £1,350, which, if they continued to add to year by year, would, if the Corporation at any time took over the workings of the Company, help to make the shares realise their full value. The Company had made a contract with an insurance company to meet any claims resulting from accidents which occurred in connection with the trams, and in the case of a woman who in the early part of the year fell from the top of one of the trams, the insurance company disputed their liability, and in the £1,350 they had included a sum of money which could be utilised in case the verdict went against them. The case had been placed before Mr. Cooper, of Manchester, for arbitration, and he hoped that the insurance company would be held liable, and that that part of the money which had been reserved this year would go back into the pockets of the shareholders next year. They had also put aside a sum of money which would meet any extraordinary demand made upon them through any damage to the line, engines, boilers, or machinery. An inspection of the line had been made that week in several places, and, as far as they could tell, it was in a satisfactory condition. Still they felt they should have this reserve fund, so that next year they would not be called upon to place anything to capital account, or to take anything out of the next year's income. If it was not required, then they would get the benefit of it in the next year's dividend, which would also be further benefited by the £235, the balance carried over to next year. If they could make the property a 7 per cent. paying concern, and also increase the reserve fund year by year, when the 21 years' lease had run out their shares would perhaps realise more than 20s. in the pound. He hoped that all would approve of the policy of the Board in putting the Company on a thoroughly sound basis.

Mr. HOYLE seconded, and the motion that the report and accounts be adopted was carried.

On the motion of Mr. HOYLE, seconded by Mr. DEAN, Messrs. Oddie and Morris were re-elected directors. Mr. J. E. Taylor was also re-elected auditor.

The meeting then terminated.

NEW COMPANIES REGISTERED.

BIRMINGHAM ELECTRIC SUPPLY COMPANY (LIMITED).—Registered by Waterlow Brothers and Layton (Limited), 24 and 25, Birchin-lane, E.C., with a capital of £100,000, in £5 shares. Objects: To purchase, on such terms as may be thought advisable, a transfer of the Birmingham Electric Lighting Order, 1889, and of the rights and powers conferred thereby, and to accept such transfer and to exercise and carry out such rights and powers and to observe and comply with all arrangements or conditions attached to such transfer and with the provisions contained in the said order. To generate, produce, sell, and supply electricity for all purposes. The first subscribers are:—G. Albright, The Elms, Edgbaston; G. Hope Johnstone, 38, Northampton-street, Birmingham; F. W. V. Mitchell, The Birches, Edgbaston; J. F. Albright, C.E., Edgbaston; Sir David Radcliffe, Thurcaston Hall, Cheshire; E. M. Shard, Beech Mount, Edgbaston; F. M. Radcliffe, 9, Dock-street, Liverpool. There shall not be less than three nor more than nine Directors. The first to be appointed by the subscribers. Qualification £500. Remuneration, £350, divisible.

THE LIVERPOOL SILVER AND COPPER COMPANY (LIMITED).—Registered by Burton and Co., 37, Lincoln's Inn-fields, W.C., with a capital of £50,000, in £10 shares. Object, the carrying on the business of treating by electrical and other processes smelting, refining, converting, reducing or assaying gold, silver, copper or other ores, mattes or regulus and metals, the manufacture of wire sheets and other forms of copper and copper alloy and for such purpose to acquire premises at Widnes, Lancashire.

CITY NOTES, &c.

EASTERN TELEGRAPH COMPANY.—This Company's traffic receipts for the month of November amounted to £60,578, as against £59,862 in the corresponding period of 1888, an increase of £716.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month of November, 1889, amounted to £44,147, and to £45,234 in the corresponding period of 1888, a decrease of £1,087.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The Directors of this Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended September 30th last, and payable on the 24th inst. The books of this Company will be closed from the 16th to the 23rd inst., both days inclusive. The traffic receipts of this Company for the week ended November 29th amounted to £5,931.

CUBA SUBMARINE TELEGRAPH COMPANY.—The estimated traffic receipts of this Company for the month of November, 1889, were £3,000, as compared with £3,107 in the corresponding month of last year. The receipts for the month of August, estimated at £2,700, realised £2,815.

DIRECT SPANISH TELEGRAPH COMPANY.—The receipts of this Company for the month of November amounted to £2,497, against £1,950 for the corresponding period of last year, an increase of £547.

GREAT NORTHERN TELEGRAPH COMPANY.—The traffic returns of this Company for the month of November amounted to £23,200. From January 1st to November 30th they were £252,400, against, in the corresponding months of 1888 and 1887, £250,200 and £242,880 respectively.

LIVERPOOL SILVER AND COPPER COMPANY.—This Company has been registered to acquire premises at Widnes, in the county of Lancaster, and to carry on the business of treating by electrical and other processes gold, silver, copper, or other ores. Capital, £50,000, in £10 shares.

NATIONAL TELEPHONE COMPANY (LIMITED).—The Directors of this Company have declared an interim dividend, for the six months ended October 31st last, at the rate of 6 per cent. per annum (less income-tax) on the First and Second Preference shares and on the fully-paid ordinary shares of the Company. The transfer books of the Company will be closed till December 17th, and the dividend warrants will be posted on the evening of the 16th inst.

STOCK EXCHANGE.—Application has been made to the Committee to appoint a settling day in, and to grant a quotation to, the Fowler-Waring Cables Company's (Limited) shares.

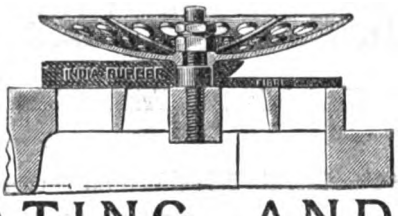
WEST COAST OF AMERICA TELEGRAPH COMPANY.—The traffic receipts of this Company for the month ended November 30th amounted to £6,600.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended November 29th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,259.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts of this Company for the half-month ended November 30th amounted to £3,089, as compared with £2,969 in the corresponding period last year, an increase of £120. Receipts for the month of August, estimated at £4,502 realised £4,529.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to **MOSSES & MITCHELL, 68-71, Chiswell Street, London.**

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 604.—Vol. XXIV. FRIDAY, DECEMBER 13, 1889. Price Fourpence.

NOTES.

Some of our friends have asked us to take up a statement, which appears in the "Medical Battery Company's" advertisement, that someone who is styled "the Assistant Editor of *The Electrician*" has written in favourable terms of Mr. Harness's Electropathic Belt. There is no legal remedy for misstatements of this sort, and we must content ourselves with a simple contradiction.

On another page will be found an abstract of Mr. A. E. Kennelly's report "On the Heating of Conductors by Electric Currents," which was read before the recent Edison Convention, at Niagara Falls. It has long been a matter of common knowledge that the Board of Trade limit of 1,000 amperes to the square inch resulted, if rigorously adhered to, in overheating in the case of large conductors, and gave too great a sectional area to the smaller wires. The exhaustive experiments of Mr. Kennelly on the safe working limit for insulated copper conductors carried in wooden panels resulting, as these experiments have, in what appears to be a trustworthy empirical formula, are, therefore, of the utmost practical value. A sliding scale such as proposed by Mr. Kennelly would certainly seem desirable.

Recurring seasons bring round the usual announcements of public lectures, and electricity claims at least an ample share. At the Royal Institution the Juvenile Christmas Course, begun by Faraday, and continued by Tyndall for so many years, is this year entrusted to the hands of Prof. Rücker, F.R.S., than whom none is certainly more able to carry on the torch of popular science. Prof. Rücker, of course, takes electricity as the subject of his six lectures. We notice that he intends to make special references to the researches of the late Dr. de la Rue.

At the Friday evening "discourses" at the Royal Institution electricity takes an unusually predominant part, no fewer than five of the ten lectures before Easter being on electrical or magnetic topics. These include an account of the "Scientific Work of Joule," by Prof. Dewar; "Problems in the Physics of an Electric Lamp," by Prof. Fleming; Magnetic Phenomena," by Mr. Shelford Bidwell; "Electrical Relations of the Brain and Spinal Cord," by Mr. F. Gotch; and "Electro-Magnetic Radiation," by Prof. Fitzgerald. In addition to this, Lord Rayleigh is to give a course of seven lectures on "Electricity and Magnetism," on Saturday afternoons, beginning in February.

Mr. Shelford Bidwell's neat experiments of the effect of electrification upon a steam-jet—or, rather, on the cloud of water spherules which appear when steam condenses into visibility—won the admiration of all the audience at the Physical Society last Friday. The peculiar and instantaneous increase in opacity at the moment of electrification, Mr. Bidwell suggests as the cause of the sudden darknesses which often occur in thunderstorms. Mr. Bidwell's research, which was conducted quite independently of some German researches on the same line, is well worthy of the attention of meteorologists.

At the same meeting Mr. Bidwell referred to the peculiar behaviour of a gas-flame when placed between the poles of an influence machine. It has long been well known that the flame points away from the positive knob and towards the negative knob. Old readers of this journal will remember a rather acrimonious discussion some years ago in which Mr. J. Johnston insisted on this phenomenon as an absolute proof of the direction in which electricity moves. All it proves is that the flame is itself not at zero potential; but the electric state and behaviour of flames are matters at present wrapped up in much obscurity.

In a very interesting Paper on "The Behaviour of Steel under Mechanical Stress," read at the Physical Society's meeting last Friday, Mr. Caras-Wilson described some experiments recently made by him, the results of which showed that magnetic induction is increased in a steel bar by submitting it to mechanical stress. The effect increases regularly with the stress and is largely permanent. The ratio of the permanent to the temporary effect also increases with the stress until, at a point below that at which the elastic resistance of the steel is overcome, the effect becomes entirely permanent. A comparison between some of Mr. Caras-Wilson's results and those obtained by Dr. Joule on the elongation of steel bars under magnetisation ("Scientific Papers," Vol. I., pages 253-256) showed that similar molecular effects are produced on steel bars by magnetisation, and by mechanical stress; and the author showed that, assuming 13×10^3 tons per square inch as the value of Young's modulus for the soft iron wire employed by Joule, in order to produce a molecular stress of the same

Digitized by Google

amount as that caused by magnetisation, an elongation 200 times as great as that accompanying magnetisation is required.

THE replies to the Edinburgh Exhibition circular recently sent out by the Committee of the Electrical Trades Section were, we hear, by no means numerous, but the terms offered by the Exhibition Committee were generally deemed acceptable.

OUR old friend the mechanical telephone has turned up again as unerringly as the big gooseberry and the sea serpent. This time he comes demanding, we hear, no less than £200,000 for his "patent rights." The great improvement which has apparently been responsible for creating this immensely enhanced value is that the diaphragm which receives the speaker's voice has now been attached to the case by means of certain spiral springs. How far this differs from the "Empire" Telephone, for which five years ago £50,000 was asked, or from the excellent "Stanhope" mechanical telephones, we do not quite understand. But that so vast an improvement should be rewarded by such a paltry sum as £200,000 passes our comprehension.

THE Silvertown strike has, it is said, completely collapsed, the Company having secured the services of fresh men to take the places of the old hands at wages for which the latter refused to work. We are extremely sorry for the strikers, although they have no one to blame but themselves, and if it be the case, as is alleged, that they paid from one-third to one-half their earnings for house rent, it would seem that action should have been taken rather against their landlords than against their employers. Surely, however, that statement must be exaggerated. The wages paid by the Silvertown Company seem to have been rather above the average for their class of workpeople; and to say that they pay half or even a third for living accommodation is simply incredible.

SPEAKING of strikes, it is not improbable that the electric light may profit somewhat by the threatening aspect of affairs in the gas industry. That, however, is not a fact on which we care to dwell with satisfaction, the supply of electricity being no less dependent upon loyal co-operation between workmen and employers than is the manufacture of gas. One thing, however, deserves noting; whatever may come of the present offer of the South Metropolitan Gas Company, permanency of contract between master and man is the only final solution of the great Industrial Problem, and it is one which sooner or later electrical undertakers will have to adopt. On this point, at least, the Gas Company deserve to be supported and imitated.

Apropos of our note last week inviting the ardent photographer to secure an authentic image of St. Elmo's Fire, we have lit upon the following passage in M. W. DE FONVIELLE'S "Thunder and Lightning":—"A photographer of Berlin had taken a negative image of the bronze statue of an Amazon vanquishing a serpent with her lance. On examining the positive proofs he was excessively surprised to see a dark streak standing out from the upper end of the lance." There seems to be some mistake in the description, for surely the streak should appear dark in the negative, not in the print. M. DE FONVIELLE gives, however, no references. Can any of our photographic readers supply us with information?

AMONGST the fancies which grew up around the loadstone in the dark ages, when its power was regarded as a species of black magic, was the notion that if it were ground to powder and dissolved in wine it brought enormous strength to him who drank it. So far as we know, nobody has yet suggested that this is the secret of the power of the rival "strongest men on earth" who are now exhibiting their feats in London. Nor if such a statement were made should we believe it. Yet "steel wine" is recognised by the medical faculty as an excellent tonic. Only, if the magnetic wine were found equally strengthening, its virtue would be attributable to the iron—not to the vanished magnetism.

SAYS the *Western Morning News* in a recent issue, "Quietly, and without much to-do, the electric wires are threading their way beneath the streets in nearly every district in London. . . . But as yet there has not been a single light to show as justification for all this vast expenditure and preparation. One day we shall hear that the last junction has been made, and with the first few revolutions of the dynamos, ten hundred thousand lamps throughout the town will suddenly blaze with light. It will be a pretty and notable sight." Indeed!

AT the Meeting of the Institution of Electrical Engineers last night, the following premiums were awarded by the Council in respect of Papers read during the past twelve months:—The Institution Premium, value £10, to Mr. W. M. MORDEY, for his Paper "On Alternate Current Working"; the Paris Electrical Exhibition Premium, value £5, to Dr. OLIVER LODGE, for his Paper "On Lightning, Lightning Conductors, and Lightning Protectors"; the Fahie Premium, value £5, to Mr. A. E. KENNELLY, for his Paper "On Certain Phenomena connected with Imperfect Earth in Telegraphic Circuits."

The International Telegraph Congress.—The next meeting of this Congress will take place in Paris next May.

The Royal Society.—The following Paper, by Dr. Hopkinson, was down for reading on Thursday, "Magnetic Properties of Alloys of Nickel and Iron."

Municipal Lighting in Germany.—The municipalities of Breslau and Hanover have decided to undertake the erection and operation of municipal central lighting stations.

York.—At the last meeting of the Town Council it was decided to proceed with the application for a Provisional Order. The capital required for lighting the proposed area is estimated at £18,000.

Airdrie.—At the last meeting of the Town Council it was decided to drop for the present the application for an electric lighting Order, and to await further developments of the electric light.

Glasgow.—On the recommendation of the Gas Committee, it was decided at a recent meeting of the Town Council to put down the capital which it was proposed to expend on the electric lighting scheme at £250,000.

Digitized by Google

Bremen.—The local tramway company has decided during the forthcoming Industrial Exhibition to lay down an electric tramway on the Thomson-Houston system, and to light the line by means of 40 or 50 arc lamps.

National Telephone Electrical Society.—At the meeting of this Society on Friday evening last, Mr. William Ollerenshaw read a Paper on "Induction Coils." The subject was illustrated by an interesting series of experiments.

Progress of the Zipernowsky System.—At the present moment 62 central stations on this system, are supplying current to 868 arc lamps and 98,385 incandescent lamps, are in operation on the Continent, principally in France and Italy.

Appointment.—Mr. Sydney T. Dobson, M.I.E.E., late senior assistant engineer on the Vienna Central Station of the Imperial Continental Gas Association, has been appointed chief engineer to the St. James's and Pall Mall Electric Light Company (Limited).

Overhead Wires in Glasgow.—At the last meeting of the Town Council a letter was received from Firemaster Paterson, calling attention to the increasing number of overhead wires. It was decided to appoint a Special Committee to take immediate action in the matter.

The International Ironmongers' Exhibition.—The full title of this Exhibition, which is to be held at the Royal Agricultural Hall on March 17th to 29th next year, is, we are informed, "An International Exhibition of Machinery, Manufactures, Appliances, and Inventions incidental to Engineers, Electricians, Builders, and Ironmongers."

Leamington.—At the last meeting of the Town Council a letter was read from the Midland Electric Light and Power Company, stating that they were prepared to continue the lighting on the terms recently proposed by the Council, and suggesting that 25 and 50 candle-power incandescent lamps should be used in lieu of arc lamps, as desired by the Council.

The Edinburgh Exhibition.—A contract for the arc lighting of the Exhibition has been arranged with the Brush Company. The lighting will be carried out by means of 350 arc lights of 2,000 candle-power. In view of a general desire on the part of foreign exhibitors, as well as of exhibitors in this country, the Executive Council have decided to grant diploma awards in all sections of the Exhibition.

Institution of Electrical Engineers.—The last Students' Meeting of the present session took place on Friday evening last, Mr. Gisbert Kapp in the chair. A Paper was read on "Electric Traction," by Mr. A. E. Childs, the discussion being maintained by the Chairman, Messrs. Barton, Muir, and Poynton. After Mr. Childs' reply a vote of thanks to Mr. Kapp terminated the proceedings.

Electricity at the Ellenborough Colliery.—Messrs. Goolden and Co. are putting in an electric light and power installation at the Ellenborough Colliery. It is proposed to have eighty 16 c.-p., six 50 c.-p., and two 600 c.-p. lamps to light up above and underground. A cable is to be run down the shaft to drive an electric pump and coal cutter. It is expected that the work will be completed in about three weeks.

Johannesburg.—The plant for the central lighting station is to be equal to supplying current to 8,000 16 candle-power incandescent lamps, and 60 500 candle-power arc lamps, with a large balance of motive-power for supplying electric motors, and to allow for additional lights as they may be required. The generating plant is to consist of twelve boilers, each of 100 indicated horse-power, and of five horizontal coupled compound engines of 170 horse-power.

The Municipal Lighting Station at the Halles Centrales.—The lighting of the Halles, according to the *Bulletin de l'Electricité*, does not give entire satisfaction: the lamps are said to be badly arranged and of insufficient candle-power. The Ferranti alternators, moreover, continue to be the subject of complaints from French electrical firms, who assert that the employment of English dynamos at the Halles is directly contrary to the regulations of the Conseil Municipal.

The St. James's and Pall Mall Company.—At a meeting of the Vestry last week a letter was read from a ratepayer, complaining of a nuisance caused by the works of the St. James's and Pall Mall Electric Lighting Company in Mason's-yard. A letter was read from the same Company, stating their intention of applying for a Provisional Order to construct two railways running under Oxford-street, one stopping at Tottenham Court-road, and the other going on to the City.

South Shields.—At the last meeting of the Town Council, the Town Clerk stated that no notice had been given with respect to providing the district with the electric light. It was, he thought, necessary on the part of the Council to give their attention to the matter during the coming year, in order that, before anybody else occupied the ground, the Council might have the opportunity of deciding whether they would secure for the town the right of providing the electric light.

Electrically Illuminated Sights for Night Firing.—The big guns turned out by the Elswick arsenal are now fitted with a device to facilitate firing at night. The ordinary sights are illuminated by a small incandescent lamp, the rays from which, passing through a lens, are converged, so that only a minute point or line of light just sufficient to distinguish the sight is obtained. By means of an adjustable resistance, the light can be modulated to suit the degree of darkness of the night or the eye of the observer.

A New Insulating Material.—A new insulating material for electric conductors has been brought out in Germany. It consists of paper which has been thoroughly soaked in an ammoniacal copper solution. The pasty mass is then pressed against the conducting wires to be covered by means of rollers, and the whole is finally submitted to strong pressure. When dry the covered wire is passed through a bath of boiling linseed oil, being left in it until the covering is saturated. This makes it elastic and impermeable to moisture.

Electricity and Veterinary Surgery.—Two members of the Vienna Military Veterinary Institute have introduced an improvement in the use of the laryngeal mirror for horses. The ordinary mirror, which at its outer end has an incandescent electric light, is introduced into the nostril, and at once makes visible any symptoms of nasal mucus and other diseases which call for the prompt isolation of the animal. The operation has proved possible even in the case of obstinate horses, and a quiet animal will submit to it without resistance.

The Maritime Conference.—At the meeting of this Conference, on the 4th inst., it was decided, by fifteen to four, to have a special fog signal for vessels not under command, or laying or picking up telegraph cables. The Committee on Sound Signals recommended on the 5th inst. that a ship not under command, and unable to manœuvre as required by the regulations, will give four short blasts. A ship engaged in laying or picking up a cable will give three prolonged blasts in succession. After discussion, the recommendations of the committee were adopted.

St. Petersburg.—The Belgian Consul at St. Petersburg states that electric lighting makes rapid progress there as well as at Moscow, in "the palaces," administrative offices, theatres, public halls, business and private houses. In the course of this summer the installation of a new central electrical station was started at St. Petersburg, as also the laying of subterranean lines. Electric lighting has been adopted in a good part of the Vibourg quarter, at the Academy of Medicine, and the Finland Railway Station, &c. The Second Tramway Company proposes to replace its steam locomotives by electric motors.

Exeter.—The dislike of the Town Council to overhead wires does not appear to have diminished. At the last meeting of the Council a long discussion took place upon the recommendation of the General Purposes Committee that the Electric Light Company should be asked to place switches at various points in their circuits, so that the superintendent of the fire brigade might be able to cut off the current in cases of urgency. Several resolutions adverse to the continuance of the overhead wire system were moved, and nearly carried, and the subject was finally dropped without any decision being arrived at.

Royal Institution.—The following are the lectures on electrical subjects arranged for before Easter:—Prof. A. W. Rücker, six Christmas lectures to juveniles on Electricity; the Right

Digitized by Google

Hon. Lord Rayleigh, seven lectures on Electricity and Magnetism. The Friday evening meetings will begin on January 24th, when a discourse will be given by Professor Dewar on the Scientific Work of Joule; succeeding discourses will probably be given by Sir Frederick Abel, Prof. J. A. Fleming, Mr. Shelford Bidwell, Prof. T. E. Thorpe, Prof. G. F. Fitzgerald, the Right Hon. Lord Rayleigh, and others.

Long-Distance Transmission in Algeria.—The municipality of Mascara (Algeria) has signed a contract for the lighting of the streets of the town by electricity. The concession is for 45 years, and the town is to pay 10,500fr. per annum for 150 16 candle-power lamps. The *concessionnaire* is given free use of the waterfall at Ain-Fekan, 30 kilometres distant, and the dynamos will have to actuate for 14 hours per day the pumps at the springs of Sidi-Daho, eight kilometres distant. The installation will thus afford an interesting example of the application of electricity to long-distance transmission of power.

Barnsley.—A correspondent writes us from Barnsley, enclosing a large yellow poster, headed "Electric Lighting and its Dangers,"—"a specimen of many hundreds that have been posted in and around Barnsley by some persons evidently not in favour of electric lighting." This document is a concise summary of Mr. Edison's recent alarmist article in the *North American Review*, and, unless its contents were taken with a grain of salt, they would, no doubt, be very unpleasant reading. We have no fear, however, that Barnsley, if it means to have the electric light, will be deterred from so doing by an alarmist poster.

Telephone Lectures.—A class has been formed in connection with the Leeds staff of the National Telephone Company, for the study of telephony and electricity, conducted by Mr. A. L. E. Drummond, the local manager. The first meeting was held on Wednesday evening, November 20, 1889, when Mr. J. C. Chambers, M.I.E.E., general manager of the Yorkshire district, gave the inaugural address. This was followed by Mr. Drummond's first lecture, dealing principally with the Léclanché Cell and its connection with the telephone. The following lectures were respectively on the "Blake Transmitter" and on "Magnetism." These lectures, which are much appreciated by the staff, are to be continued each Tuesday evening throughout the winter months.

Overhead Telephone Wires as Lightning Protectors.—It would seem, according to a recently-published correspondence between Dr. Stephan and the Madgeburg Insurance Company, that a overhead telephone system forms a very effectual protection against lightning. From 1883 to 1888 there has only been one case of damage by lightning in the centre of Hamburg, where the wires are dense, while there have been numerous instances in the suburbs. A similar immunity has been experienced in Berlin, and other towns where there are large numbers of overhead telephone wires. Dr. Stephan points out in this correspondence that the German telephone systems are constructed with the greatest care and are well provided with lightning arresters.

The Kensington Electric Lighting Mains.—At the last meeting of the Kensington Vestry, the Works Committee reported having considered a drawing of cover proposed to be put down in the roadway at the entrance to Kensington Court, by the Kensington and Knightsbridge Electric Lighting Company, such cover being 3ft. 6in. square, and recommended that the sanction of the Vestry be not given for the laying of any covers in the roadway of the size of the one mentioned. Attention was called to the nuisance caused by pipes lying in the roadway. The Surveyor said it took him quite one hour and a-half a day to write and look after these Companies. After several complaints on the part of various members of the Vestry, it was decided that a strong letter should be written to the several Companies.

Exports of Electrical Apparatus, &c.—The Board of Trade returns for November are again very satisfactory as regards the exports of telegraphic wires and apparatus connected therewith. Not only do the figures for the month of November compare very favourably, but the aggregate value of our exports this year is very much in excess of the corresponding amount on November 30, 1888 and 1887. We append a comparative statement for the past three years:—

	1887.	1888.	1889.
Jan. 1st to June 30th	£188,812	£244,213	£576,456
July 1st to Sept. 30th	468,252	152,926	117,460
October	31,475	17,938	205,603
November	14,089	18,566	113,306
Eleven months	£702,628	£432,743	£1,012,825

Proposed Cable between Cayenne and the Antilles.—A very interesting question was settled in the last Session of the General Council of Cayenne. This Assembly has voted an annual subsidy of 80,000fr. in favour of the submarine cable company which has undertaken to lay within a year of the signature of the convention a submarine cable between this colony and the French Antilles. The same company has made contracts with Martinique and Guadaloupe, which substitute it for the English company now bound to maintain telegraphic communication between France and the Antilles, and which company's privilege expires at the end of this year for Guadaloupe, and in 1892 only for Martinique. We may therefore anticipate that French Guyana will be connected with the Antilles, and consequently with the general system, in a few months.

The Telephone in Germany.—Telephone exchanges are now established in 176 towns in Germany, the total number of subscribers being 33,460. The following are some interesting statistics with regard to the four principal towns:—

	Subscribers.	Messages per day.
Berlin	9,534	187,371
Hamburg	3,574	80,181
Dresden	1,566	24,946
Leipzig	1,235	25,496

Trunk lines with 10,751 kilometres of wire connect 169 towns. On the Hamburg-Leipzig trunk wire there are on an average 362 calls per day, on the Bremen-Bremerhaven wire the average is only 292, while between Cologne and Bonn it is 235, between Berlin and Hamburg 213, between Kiel and Flensburg 13, and between Berlin and Dessau only 5.

The Drummond Railway Signalling Device.—A very simple and effective apparatus has been devised by Mr. Dugald Drummond, of the Caledonian Railway, and has been tried by him experimentally with good results. The apparatus consists essentially of a guide bar fixed on the road at a slight angle to the rail, and a trigger carried on the locomotive. When the guide bar is raised the trigger slides along its edge, and is gradually pushed sideways until it trips a locking catch and releases a rod which is subject to the action of a spring. This rod may be connected to a valve, when the train is fitted with air or vacuum brakes, or it may carry electrical contacts to set a gong in action. In the former case the brake is applied automatically on passing a signal set to danger, and in the latter the driver is warned that he has not a clear road before him. The cost of fitting the apparatus to a locomotive is said to be very moderate.

The Electric Light at the Royal Castle of Pelesh.—The Castle of Pelesh, which is the country seat of the King of Roumania, and is some 80 miles north of Bucharest, contains a very complete electric light installation. Power is obtained from a waterfall close by. The plant comprises three 150 ampere 110 volt Edison machines; a 10 ampere 800 volt Brush machine; a self-excited Gramme alternator, giving 100 volts and 28 amperes; and a shunt-wound Gramme machine, giving 20 amperes and 110 volts. The dynamos are driven by Girard turbines, and the mains are lead covered. The lights comprise 685 incandescents of various candle-power, and 100 Jablochkoff candles. Twenty-five 100 candle-power incandescents light up the approach to the castle for a distance of 1,000 yards. The Royal Palace at Bucharest has also been lighted by the electric light since 1883, 1,580 10 candle-power incandescents being installed.

Government Telegraph Code for India.—A publication, called "Telegraph Word Code," has, says the *Indian Engineer*, been compiled for the Government of India, under the

Digitized by Google

orders of the Director-General of Railways, by Mr. F. B. Hebbert, Assistant Director-General of Railways, for use on Indian State Railways, which it is desired to bring in use as fast as it is found convenient, with a view to reducing the expenses incurred on Public Service messages sent over the wires of the Telegraph Department. The first section of the pamphlet is intended specially for use in transmitting telegrams concerning returns called for from the railway administrations throughout India, and will be brought into use at once. The abbreviations accepted by the Railway Conference of 1888 for use as code initials for the principal railways and railway stations in India have been embodied in the publication, and similarly the names of returns, &c., have been so abbreviated that the method will greatly reduce the work thrown on the Telegraph Department.

Dockyard Central Lighting Stations.—In the forthcoming Navy Estimates, says the Portsmouth correspondent of the *Times*, a sum of money will be asked for to provide an important and much-needed improvement in Portsmouth Dockyard. The work below decks in ships after being launched is comparatively slow in consequence of the obscurity in which it is carried on. When the work in progress is so far advanced towards completion that the steam power of the ships can be brought into requisition, or where ships are docked for repairs, it is customary to make use of electric lamps. But it is obvious that in periods of emergency, when it would be of paramount importance to get ships ready with the utmost despatch, the work of preparation would have to be continued throughout the night, and with all speed. It is now proposed to erect central electric stations in connection with the various docks and basins, so that ships repairing, refitting, or completing for sea may be brought close at hand and their own wires connected with the stations.

The Buenos Ayres-Monte Video Telephone Line.—The trunk line connecting Buenos Ayres and Monte Video was opened with considerable ceremony on October 26th. This line, which is 186 miles long, is worked on the Van Rysselberghe system. The work of construction was entrusted by a private company to M. C. Laborde, and the Felten and Guilleaume cables and bronze wires were supplied by Messrs. W. F. Dennis and Co., of Billiter-street. The line is carried on posts along either side of the River Plate from Buenos Ayres and Monte Video respectively, to the points where the river is crossed. The connection here is established by means of submarine cables, which cross the river at a breadth of 28 miles. In the vicinity of Monte Video the bronze wire spans a distance of 460 yards across the river Santa Lucia, by means of poles 108ft. in height. The charges for the use of the telephone are worthy of notice. During the busiest part of the day they are as follows:—For five minutes' use $5, for five to 10 minutes' use $12 50c., for 10 to 15 minutes' use $25. The line has so far given satisfaction both as regards articulation and loudness.

Curious Treatment of an Electric Meter.—An action was recently brought by Messrs. Chamberlain and Hookham against Messrs. Scott and Co., of Jermyn-street, to recover £16. 5s., the price of an electric meter. The meter was made by the plaintiffs according to a patent by Mr. Hookham, and supplied to and accepted by the defendants. No complaint was made about its working until application was made for payment. Defendants then wrote that the meter would not work. Plaintiffs sent their engineer to see the meter, and he found that a gardener was in charge of it, and he used it as he would a hot-water pipe. The engineer carefully examined the meter, and had it set right, but the meter would not work. He then discovered that it had been switched out of circuit, but the moment the current was turned on the meter worked correctly. Further complaints, however, were made by the defendants, and plaintiffs sent word to them to let the meter alone, and not let the gardener manure it, and it would then go all right. The defence was that the meter would not act properly under any circumstances. Verdict for the plaintiffs.

The National Telephone Company.—On Friday last the eighth annual assembly of the National Telephone Company was held in the St. Andrew's Halls, Glasgow. Over 300 attended, and amongst those present were Sir William Thomson, Messrs. W. Alex. Smith, resident director, D. Johnston Smith, district secretary; W. R. W. Smith, D. Sinclair, district engineer. During an interval Sir William Thomson expressed regret at the unavoidable absence of Colonel Jackson, whose health had broken down through the great stress put upon it in managing such a gigantic and progressive concern as the National Telephone Company. The past year, he said, had been an eventful one in the Company's existence, as during that time the three leading companies in Britain had amalgamated, and there were still pending negotiations for a further amalgamation. The National Telephone Company had 32,000 miles of wire in connection, while the "calls" were 73,000,000 per year, which was equal to 380 "calls" per minute, or more than six per second. In Scotland they had 54 towns connected with their exchange, and with the addition of Dundee, which would be made in two months hence, they would be able to speak with 55 different places. They had also hopes of overcoming the difficulty in connecting with Ireland. The present obstacle was the expense of laying 30 miles of cable, but he believed that by another year the expenditure necessary would not be found to be a barrier.

The Eickemeyer Storage Battery.—This battery consists of a flat cast-lead plate foundation provided with a number of polygonal-shaped holes. These openings are lined with active material which is well packed around plugs, which, when removed, leave central circular openings. Each plate has a projecting terminal and all are counterparts cast from the same pattern, so that when reversed in position and piled one on another with the terminals located alternately on opposite sides, the holes register with corresponding holes in all the plates throughout the pile. Between each two plates there is placed an insulating plate, which is also provided with holes corresponding to those in the lead plates. With the battery thus constructed each vertical line of holes constitutes a chamber for containing the electrolyte, and this is supplied by means of a funnel which tightly fits the feed aperture at the top. As the liquid falls to the bottom of the battery it is distributed by way of lower channels and openings in the base-plate to the several cells, in which it rises with uniformity until all are properly filled. An extensive area of the porous material is thus exposed to the electrolyte, and the metallic lead of each grid is completely protected against the liquid except through the active material. Mr. Eickemeyer has designed various forms of these cells, all embodying the same principles, and resulting, it is claimed, in a cell of considerably reduced weight in proportion to its storage capacity.

The Specific Resistance of Amalgams of Sodium and Potassium.—In these investigations, says Prof. Grimaldi in *Il Nuovo Cimento*, I determined the electrical resistance of several amalgams of sodium and potassium of different degrees of concentration, with a view of ascertaining their chemical constitution. The determinations were effected either by the Wheatstone Bridge or by Kirchoff's method. The amalgams were contained in U-shaped glass tubes, and minute precautions were taken in drying and in filling the tubes. I noticed that amalgams, rich in sodium and which solidified, had a specific resistance less than that of pure mercury. But if the resistance of an amalgam is determined at 0°C. before and after heating, its latter resistance is found to be higher. This permanent increase in resistance is proportionate to the intensity of the heat applied and to the duration of its application. This would seem to indicate that these amalgams are composed of two distinct parts, which are separated by heat. Liquid amalgams containing but a small amount of sodium, and prepared by the direct union of the two metals, have a higher specific resistance than pure mercury. The resistance of two amalgams, one of which contained twice as much sodium as the other, was found to be the same. On the other hand, the resistance of liquid amalgams, obtained by dissolving crystalised Na_2Hg_{12} in mercury, became less as the quantity of sodium was diminished. This difference leads one to suppose that there exists a definite liquid amalgam containing a small amount of sodium, which is confirmed by the fact that two amalgams, equally rich in sodium but prepared by two different processes, showed different resistances.

REVIEWS.

The Alternate Current Transformer in Theory and Practice. By J. A. Fleming, M.A., D.Sc., Professor of Electrical Engineering in University College, London, &c., 8vo., 487 + xii. pp. (London: "The Electrician" Printing and Publishing Company, Limited, 1889.)

(Concluded from page 111.)

Continuing this section of Chapter II., Dr. Fleming then treats of the magnetic properties of iron. It seems a pity, in view of modern modes of thought, that the subject of magnetic permeability should have been approached by Dr. Fleming through the antique road of surface distribution of free magnetism and the notion of susceptibility. Let the magnetising force at any point be called **H**; the meaning of this symbol is best comprehended by the ideal process of placing a unit magnetic pole at that point and measuring the number of dynes of force with which it is urged forward by the magnetic action. To say that the intensity of the magnetic force is **H** means that a unit pole placed there would be acted on with a force of **H** dynes. In the medium of which the properties are taken as a standard, namely air, the convention adopted is this: that we may draw as many lines through unit area as there are dynes on unit pole. But if the medium is one of higher magnetic power, the number of magnetic lines which result from the same magnetising force will be greater, and is called **B**. The coefficient which represents the ratio of **B** to **H** is called the permeability of the medium, and the usual symbol for it is the letter μ; so that $\mathbf{B} = \mu \times \mathbf{H}$. So that if the magnetising force were such as to evoke **H** lines to the square centimetre in air, there will be μ times as many in the iron. This idea is of the simplest kind. When the old ideas were prevalent (as they still are in the academic text-books and on the Continent) that the "free magnetism" is something residing on the surface of the magnet, plastered on, as it were, over the ends and adjacent parts, it was convenient to employ a symbol —usually the letter κ—to indicate how many units of surface magnetism there would appear on the end surface per square centimetre when the iron was subjected a uniform longitudinal magnetising force **H**. Calling the number of surface units per square centimetre **I**, one then had the relation $\mathbf{I} = \kappa \times \mathbf{H}$. After this, since each surface unit of magnetism on the end of the magnet corresponds to the passage through the surface of 4π magnetic lines, it becomes clear that the number of lines which the presence of the iron adds to those that there would have been in air is $4\pi\mathbf{I}$ per square centimetre, or that to the original **H** the iron adds $4\pi\kappa\mathbf{H}$ lines. Hence the whole number of lines passing through the square centimetre, where the magnetising force is **H**, will be $(1 + 4\pi\kappa) \times \mathbf{H}$. Having got so far, one is then told that this complex factor is called the permeability, and symbolised by the letter μ. But why all this roundabout way of leading up to the simple idea of permeability? The notion of susceptibility which intervenes is never wanted in modern practice, and is, in fact, a more or less misleading notion, as it makes beginners think more of the accidental surface phenomena and less of the real permeation of the magnetism through the interior. Having made this criticism, it is more pleasant to add, that in the data that follow about permeability curves and their difference in different materials, the matter is abundant and the manner of presentation quite satisfactory. So, also, is the second section of this chapter, relating to the induction of currents, or, rather, of electromotive forces, down to near its end. The effects of self-induction in a circuit, and the modes of exhibiting its action, are very carefully and clearly explained, with diagrams illustrative of experiments on the point. We come, however, at page 51, upon a matter where Dr. Fleming departs, as it seems to us unwisely, from a usage which, though of modern date, is certainly accepted by many able teachers. Dr. Fleming uses the word "inductance" as if it were the synonym of "coefficient of self-induction." We are not going to accuse Dr. Fleming of any confusion of ideas, either in his own mind or in his writing; he knows perfectly well, and has stated clearly in other places in his book, that the effects of electro-magnetic momentum in retarding the phase of periodic currents, and in diminishing their amplitudes, are dependent upon the coefficient of self-induction and upon the periodicity of the current; nay, more, that the two factors periodicity and coefficient of self-induction come in with absolutely equal weight into the expression for the retardation of phase and into the expression for the diminution of amplitude. Both these effects depend upon the ratio between the resistance of the circuit and the quantity which is ordinarily expressed by the symbols $2\pi n\mathrm{L}$, where n is the periodicity or number of alternations per second, and L the coefficient of self-induction. Now, the term "inductance," as mostly used, is applied to the whole of this quantity, the impedance, or virtual resistance in the circuit being made up partly of true resistance and partly of inductance, being, in fact, the square-root of the sum of their squares. The angle of lag can then be defined as that angle whose tangent is the ratio of inductance to resistance. Dr. Fleming's new use of the term inductance robs us, however, of this convenient way of stating these matters. It is to be hoped that he will reconsider the point before issuing a second edition. As a rule, Dr. Fleming is very careful in observing the distinction—so greatly neglected by Continental writers—between work and rate of doing work. There is, however, an ambiguity on page 53, where it is not clear whether $d\mathrm{E}$ is used for an element of work or for an element of rate of work. The use of the symbol E for work is in itself unfortunate.

It is gratifying to note that Dr. Fleming has the courage to adopt and use the expression "magnetic resistance" for the ratio of the line integral of the magnetising force to the total magnetic induction in a magnetic circuit; the more so because the objection that has been taken to the use of this convenient term is based on a fallacy.

Those whose knowledge of the theory of electricity and magnetism is of the academic order will receive rather a rude shock when they discover from page 55 that the three modes of defining the coefficient of self-induction, which academically are identical, lead to three different values in the case of real magnetic materials. A summary of the researches of Dr. Sumpner on this matter is given, together with a discussion of the relations between the coefficients as variously defined, and the curves of magnetisation.

An excellent summary of the researches of Ewing on hysteresis closes Chapter II. It is a pity that the subsequent data on p. 287 were not included with those in this earlier section.

The third chapter of Dr. Fleming's work is devoted to the theory of simple periodic currents, and opens with an exquisitely clear and complete account of harmonic motion in general, and of Fourier's theorem in particular. This section might with advantage be studied by all teachers of mathematics as an example of the way to let the light of common sense illuminate an abstract topic, which is too often made repulsive to the beginner by the bald and uninteresting mode in which it is presented. It is true that Dr. Fleming does not scruple to make use of either the notation or the methods of both differential and integral calculus when the occasion requires. And he is quite right too. The engineer, whether mechanical or electrical, who has not grasped the fundamental ideas which are conveyed by the two symbols the little d and the long $\int$ is distinctly the mental inferior of him who, whether he actually uses the symbols or not, knows the significance of the two operations. They are as essential to the intelligent understanding of the facts of Nature as are the operations denoted by the symbols $\div$ and $+$, which operations many persons perform continually without actually using the symbols. Unfortunately, the British schoolboy is handicapped, as compared with his continental compeers, by having to spend weary months on "long" division and "long" multiplication, "reduction," and other brain-wasting rules, from which his rivals are preserved by the happy accident of possessing a rational system of weights and measures in which there are no tables to learn and no reductions save by multiples of ten. So the British schoolboy is altogether denied at school any inkling of even the elements of the calculus, though logically he ought to begin this before he attacks trigonometry. Nature, however, asserts herself in spite of national prejudice and academic conservatism. It is impossible to take many

Digitized by Google

steps into the study of natural facts without realising the necessity in some shape of dealing by some sort of a calculus with the variations of things, simply because in Nature things do vary, and increase, and decrease. True, the mathematical prudes try to keep back from the mind as long as possible the use of the simple natural language for expressing facts about variation and increments and the integral sum of the increments. They foist upon him, so as to prevent him learning or using the sacred symbols d and $\int$, dry and dreary pages of long-winded algebraical "proofs," in order to establish some point for which two lines of crystallised common sense in the shape of a most elementary integration would have sufficed. And the result of their prudery is that the British schoolboy grows up with a sort of shuddering dread of the little d and the long $\int$ as of something which only a university man can tackle or understand. "It is generally easier," says Dr. Fleming, "to master the elements of the calculus than to construct or follow proofs which aim at avoiding its use." We heartily commend this golden sentence to the thousand teachers of academic mathematics who are still trying to drive their bewildered and belated pupils along the narrow path of Todhunterian method, or through the tortuous defiles of the so called "geometrical" conics, that hybrid study which is neither purely geometrical nor analytical, but which uses complex algebraic proofs to demonstrate matters that are far more simply proved by the most elementary calculus. Dr. Fleming is here no unworthy follower of Clifford. Those who prefer that things should be taught in old-fashioned ways, and do not value modern methods of teaching, may spare themselves the trouble of reading Dr. Fleming's book. Using, then, both the notation and the methods of the calculus, but elucidating every point both by geometrical illustrations and by clear explanatory remarks, Chapter III. proceeds to establish the laws of current growth in inductive circuits. These include both the case where the electromotive force of finite amount is suddenly applied—as by the switching-in of a battery of cells—and the case of a periodic electromotive force, such as that of a simple alternate-current generator. The differential equations are built up bit by bit and duly integrated, and so page 109 brings us to the well-known rule for sine-currents, with the modification of Ohm's law, wherein impedance takes the place of resistance. Here a sentence or two might have been amplified with advantage; but the geometrical illustrations which follow atone for the previous brevity. The illustrations from pages 120 to 125 of the give-and-take of power in the four stages of a complete period of alternation of the current are excellent. So is the geometrical method of treating the mutual induction between two circuits which follows. The use of the clock-diagram for studying harmonic motions, due originally to Thomson and Tait, and applied by Blakesley and by Kapp to the study of alternate-current problems, is here greatly developed: it virtually becomes in Dr. Fleming's hands a graphic theory of the alternate-current transformer. It seems a pity that whilst the ordinary spark coil is fairly fully treated on pages 181-191, the theory of the use of the condenser in conjunction with it is given, without any cross-reference, on page 383.

One omission we notice, namely, the absence of any direct account of the effect of self-induction in smoothing out the ripples in the waves of electromotive force. This omission is the more curious, as the careful statement of Fourier's law in the early part of the work had paved the way for treatment of this topic.

Chapter IV., which occupies the middle third of the book, opens with a narration of a number of purely experimental researches. Here we have by far the best and most complete abstract accessible to students of the researches of that truly great man, Prof. Henry, who has hitherto received far too faint a recognition for his work on current induction. His investigation of the higher order of induced currents is better known than some of his other researches. He discovered and most distinctly describes the use of the induction coil, so arranged as to give out from the thick-wire secondary a larger current (but at lower pressure) than the current imparted to the fine-wire primary, or, as he expressed it in the not too precise language of that time, he proved that an intensity current can induce a quantity current. From this Dr. Fleming goes on to the theory of the spark-coil, where, instead of an alternating electromotive force, an abruptly intermittent one is applied to the primary wire by means of a self-acting rapid break. This leads to the researches of Breguet and Masson, and to the more modern investigations of Blaserna, Helmholtz, Hughes, Grant, and Willoughby Smith, together with brief references to the mathematical writings of Lord Rayleigh and Mr. Oliver Heaviside; and these lead again to the later experiments of Hughes, and the fact now amply established that periodic currents, unlike steady ones, do not flow equally through the whole cross-section of the copper conductor, but seek the outside layers, so distributing themselves through the cross-section as to make the self-induction a minimum. The action of "choking-coils," and the influence upon them of tbe variations of permeability in their iron cores, is next considered. From this point Dr. Fleming turns back once more to the subject of transformers; this time to deal with them as containing iron cores, the clock-diagrams coming in again, but modified so as to take in the additional facts. There is, doubtless, an advantage in this order of treatment; but it is a little unfortunate that the three passages of the book, namely, pages 146-154, 269-282, and 302-304, which give the theory of transformers, firstly, with air circuits; secondly, with iron circuits; thirdly, with iron and air circuits, are not all consecutive. It is still more unfortunate that the notation used in them is not quite consistent; for example, N sometimes stands for the coefficient of self-induction of the secondary circuit, and sometimes for the number of windings in a coil. Brief references are given to the several tests made on actual transformers by Ayrton, Cardew, and Ferraris.

Chapter V., which forms the last third of the book, is of a more speculative order, being devoted to the dynamical theory of current induction: that is to say, it deals with those modorn views of induction phenomena which have resulted from Maxwell's study of Faraday's researches and opinions. These modern views have lately been independently treated of by Prof. Oliver Lodge in his own inimitable manner in the volume lately reviewed in these columns.* It is interesting to have in Dr. Fleming's work another account of the same field of investigation. Maxwell's theory of electric "displacement" as the equivalent, in a dielectric, of the ordinary current in a conductor, is the key-note to his later theory of molecular vortices. We have here explained to us by Dr. Fleming the mechanical model which Maxwell imagined for the purpose of explaining the phenomena of electro-magnetic induction, all space being considered as made up of elastic wheels geared together with intermediate "idle" wheels, a mechanism which Prof. Lodge has lately somewhat developed. Maxwell's electro-magnetic theory of light, which resulted from his study of the necessary equations for expressing the properties of the electro-magnetic field, naturally follows in due course, and is succeeded by a discussion of electric oscillations, of the recent researches of Prof. Lodge and of those of Prof. Hertz, which have lately claimed so much attention from the scientific world. Of these a very full account is given; being, indeed, an almost complete transcript of the excellent abstract by Mr. de Tunzelmann, which originally appeared in *The Electrician*.† After this Dr. Fleming brings his first volume to an end, with a few closing remarks on the modern views. In respect of these there is no fundamental difference between him and Dr. Lodge; indeed, the facts give no room for much difference. No electrician who has taken the trouble to study the facts, and who has the capacity to follow their inescapable consequences, can fail to learn that the energy of a so-called electric current is not transferred longitudinally along the substance of the conducting wire (as used to be supposed), but is transferred into it sideways, travelling, not along the wire, but across the insulating medium which surrounds it. The truth that insulators convey the energy and do not dissipate it, whilst conductors (so-called) dissipate the energy and do not convey it, is a hard saying te the half-educated electrician. Yet it is the legitimate outcome, as Dr. Fleming says, of that half-

century of scientific thought which dates from the period of Faraday's conception of an electro-magnetic medium.

When Dr. Fleming gives us his second volume, he may fill it with an equally excellent account of the practical work that is being done with transformers for the purpose of distributing electric energy for lighting, welding, and motive power; but we venture to doubt whether his second volume, however excellent, can have the value of his first in educating the electrical engineer in modern developments and progressive views. Some of the points which have called for criticism arise from the fact that portions of the book were written as serial articles for the press. That the completed work should show so little trace of this is greatly to its author's credit. His historical notes of reference are numerous and excellent, and absolutely devoid of partiality. It is a book which the electrical engineer of the present and of the future alike will read—he of the present, if he can; he of the future, because he must.

SILVANUS P. THOMPSON.

A COMPARISON BETWEEN THE CONTINENTAL, AMERICAN, AND ENGLISH DYNAMO-ELECTRIC MACHINERY.

BY ALBION T. SNELL.

(Concluded from page 59.)

The Continental dynamos have several details differing widely from English practice. Amongst these the solid bearings with metal discs fixed to the journal for distributing the oil may be mentioned. This style of automatic lubrication is very general in France, and is used in a modified form by the Edison Company in America. (*The Electrician*, September 6th, p. 446). The Oerlikon machines have ordinary split bearings of round design. A peculiar feature of many machines is the use of a *gravity* brush, somewhat like that adopted in the Parsons' steam turbine dynamo. For many purposes these brushes seem to work very satisfactorily; but the armature must evidently be fairly free from vibration. Another type of brush also very common on the Continent is shown in Fig. 15, which illustrates the Alsacienne brush-holders. It will be seen that the brush and its holder are carried by a long curved spring. The pressure on the commutator can be adjusted either from the pin carrying the spring, or by shifting the brush itself in the holder. This design seems to work well. It is extremely simple, and should find favour amongst English designers. I have not seen the principle applied before. The brushes are sometimes made from brass, and sometimes copper: both metals seem to be equally favoured. Copper gauze is used by a number of firms, and generally wears well. Gauze brushes are just now the *thing* amongst us. I imagine, though, they will have their day. Experience seems to show that no one type of brush will suit every class of machine. The character of the work has no little influence on the results obtained, and the indiscriminate use of any particular style of brush cannot meet with complete success. With motors subject to very large variation of load and intermittent work, the carbon brush appears to be the most successful, if we may believe the high praise given them in America as well as on the Continent. For motors running with a fairly constant load, probably thin copper plates at a tangent to the commutator are the safest. Copper gauze is excellent as long as it keeps cool; but if sparking once commences the fragile material is soon destroyed.

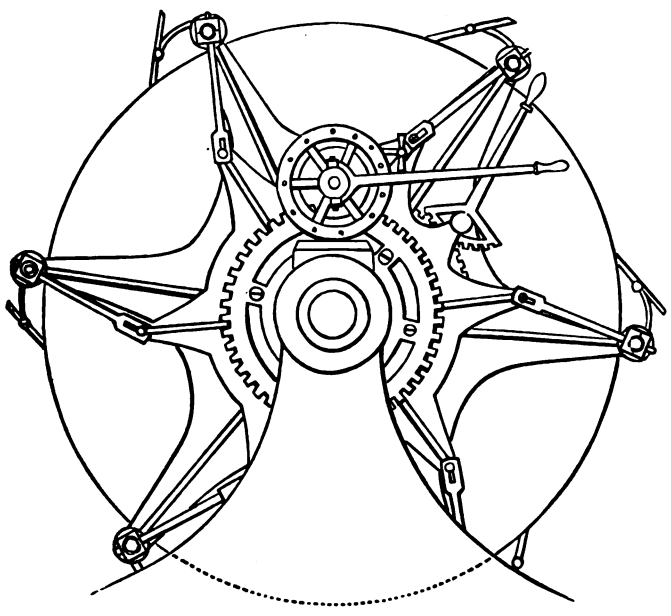

FIG. 15.—Brush-holder of the Alsacienne Dynamo.

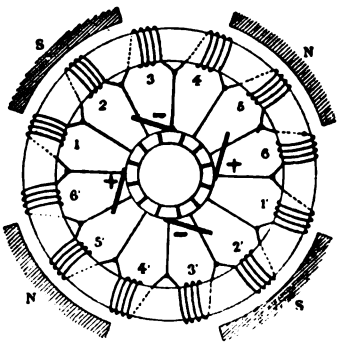

FIG. 16.—Four parallels, four brushes.

The different commutators in the Exhibition were a study in themselves. There were pure copper forgings, cast segments in copper, and bronze alloys, and segments cut from cast rings. The Alsacienne Company, on their two-pole over-type dynamo of 60,000 watts, have a commutator built up of a fine, hardened iron. This latter has the segments fixed by screws to insulated pieces of brass, which are connected with the armature winding, the insulation between the segments being air. The segments overhang from the point of output, and so are insulated by an air space from the shaft. The machine seems to run well, and is practically sparkless.

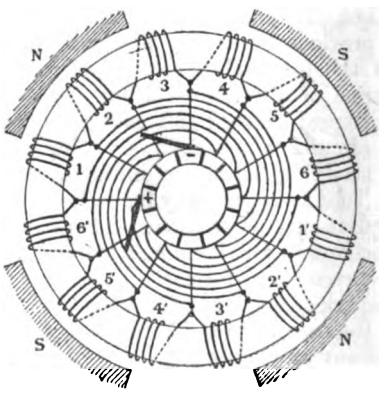

FIG. 17.—Four parallels, two brushes.

The insulating materials used on the commutators were various—mica, asbestos, and vulcanised fibre. In England asbestos has almost gone out for insulating commutators, mica being almost invariably employed instead, while vulcanised fibre is used for the rings. With a few notable exceptions the Continental commutators appear to be inferior in workmanship and design to those made in England.

The windings of the armatures and fields of both Continental and American machines are, as a rule, not so carefully carried out as those of the best firms amongst us; but in most cases the work is sound, if rough. Some firms, however, turn out their winding with a finish equal to the best in England. Amongst these the Oerlikon, Thury, and Alioth Companies are specially notable. The Continental Edison do not seem to

Digitized by Google

pay such attention to this detail as the parent company does. The American Edison high-tension drum armatures are masterpieces of this difficult branch of the electrical trade. The Thomson-Houston arc dynamos must also be very carefully wound to stand such high tensions. The incandescent, alternating, and welding dynamos by the same company are now well finished in this respect. The early machines shown in Europe were very rough.

In England there seems to be mainly two methods of winding, both having closed coils. The first is the well-known Gramme winding, which is applicable to ring, cylinder, and disc armatures, with two or more poles. The second is adapted for drum types, and is usually a modification of the Alteneck method, and practically is only used with two-pole machines. In America also,

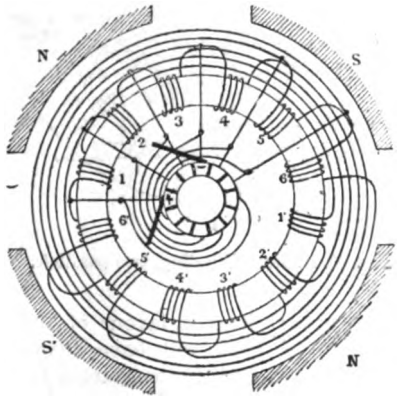

FIG. 18.—Two parallels.

excepting the Brush and Thomson-Houston Companies, the practice is similar. The Edison drum winding is really only a modification of the original idea of Siemens. Continental engineers seem to have used these simple windings to a large extent also; but the extensive use of multipolar machines has led to the invention of several very interesting methods of winding not very well known over here.

I am indebted to an article by M. W. C. Rechniewski in No. 24 of *La Lumière Electrique* for 1887 for some of the following diagrams. Whether the complications involved in some of them are worth the results gained only experience can show in

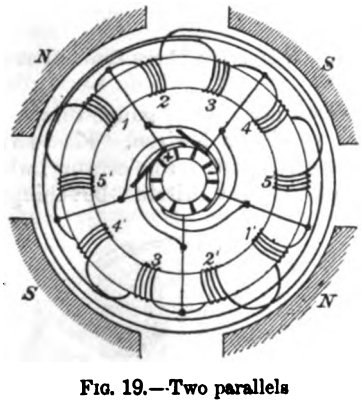

FIG. 19.—Two parallels

a conclusive way; but they are certainly ingenious, and merit some study. To properly appreciate them, it will be necessary to start from the simple designs in general use for multipolar machines. Fig. 16 is a diagram of a four-pole cylinder armature, with four brushes, the opposite brushes being of the same sign. In practice this winding is used for large currents and relatively low potentials. The opposite brushes are coupled in parallel. The Gülcher dynamos are wound in this style. Fig. 17 is the diagram of a similar winding, with the coils also coupled in four parallels. But opposite coils of the same potential are coupled together, and only two brushes are really necessary. Four brushes are, however, a convenience in practice, for two can be kept in reserve. This coupling is due to Mr. Mordey, and is used in the Victoria Dynamos. Fig. 18 shows one method of coupling the coils in two parallels. This arrangement gives a tension twice as great as that shown in Fig. 17 for a given number of turns of wire—the current, of course, being correspondingly reduced. It will be noticed that opposite segments of the commutator are joined together, and that opposite coils are also coupled in series. The connections are somewhat cumbersome, but the winding is symmetrical. Two brushes only, at 90° to each, are generally used. Figs. 19 and 20 are simplifications of this design. Alternate coils are connected to alternate segments of the commutator, and opposite segments of the commutator are joined. It will be noticed on carefully inspecting these two diagrams that, in order to make the winding symmetrical, it is necessary that the number of coils on the armature be not a multiple of the number of pairs of field poles. Fig. 19 illustrates

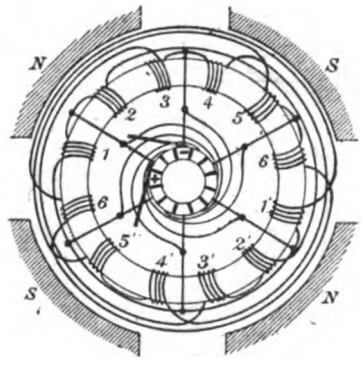

FIG. 20.—Two parallels.

the symmetrical winding; Fig. 20 the unsymmetrical. In both methods there will be an unequal resistance in the two parallels, since one pair of coils will always be short-circuited by one of the brushes. This difference is a matter of no importance, if the the coils be as numerous as usually obtains in practice.

Fig. 21 shows a modification of the multipolar ring winding. Each coil is connected to n segments at intervals of $\frac{360}{n}$ degrees, where n is the number of pairs of poles in the field. This winding enables the number of commutator bars to be

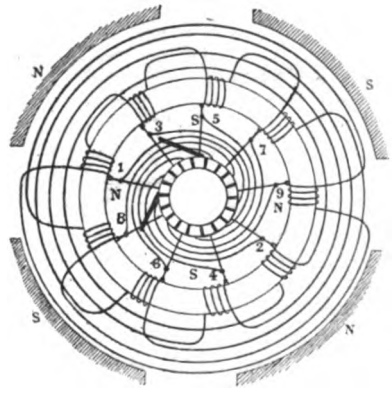

FIG. 21

increased without a corresponding increase in the number of coils. I very much doubt whether the point at issue is worth the trouble and complication of the troublesome connections. What these latter must be in practice can be imagined by inspecting Fig. 21.

This winding, adapted to a disc, is said to give extraordinary results in the Desrozier machine. A partly-finished diagram of the winding is given in Fig. 22. Note the connections, and recollect this armature consists of two complete discs with separate windings.

The Alioth winding presents several features in common with the two preceding designs; it, however, is adapted to a drum core. The diagrams for parallel and series connections are given in Figs. 23 and 24. They are copied from *The Engineer*

Digitized by Google

In an armature of 10 coils wound in four parallels the current divides as follows: starting from the negative brush it passes through the coils in four groups of two in series, two coils being short-circuited by one of the brushes. The poles are formed at the spaces covered by these two coils. Assuming the positive brush in connection with coils 3, 2, 8, and 7, the negative brush will be in connection with coils 1, 6, 4, and 9, and 5 and 10 will be short-circuited on themselves by one brush. In two parallels with the same number of coils the order of the coils is as follows: 1, 6, 7, 2, and 4, 9, 8, 3.

10 and 5 are again short-circuited by the negative brush, and they are in series with each other. The brushes are in

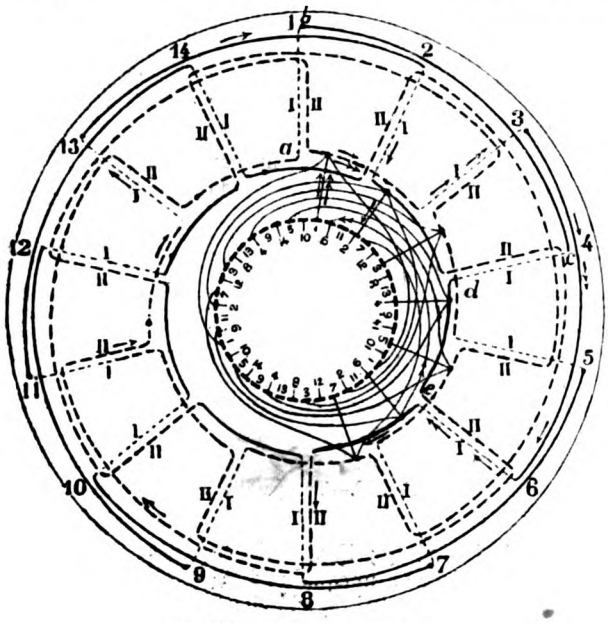

Fig. 22.—Desrozier's Winding.

each case at 90° to each other, because coils in relatively the same positions, *i.e.*, at distances of 180° to each other, are coupled.

The similarity to the ring winding in Figs. 20 and 21 is apparent.

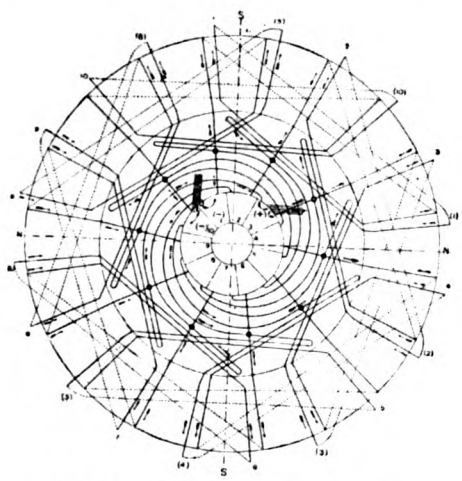

Fig. 23 —Alioth Winding, four parallels.

Fig. 25 shows an end view of a four-pole Thury drum armature winding. This design merits a close study. It will be noted that coils of largely-differing potentials are not so much in contact with each other as in the ordinary drum winding. And since the coils can be wound on shapes before being put on the core, the insulation can be made very secure. The Thury armatures shown at the Exhibition were most workmanlike, and formed a striking contrast to some of the French work. Fig. 26 is a diagram of the new Edison disc winding, patented in 1887. The arrangement is really a modification of the diagram Fig. 22. The connections are simple, and so far are a considerable improvement on the Desrozier design; the chief objection appears to be a possible difficulty in the mechanical structure.

Attention has been drawn in these articles to some of the chief features of Continental and American practice. The

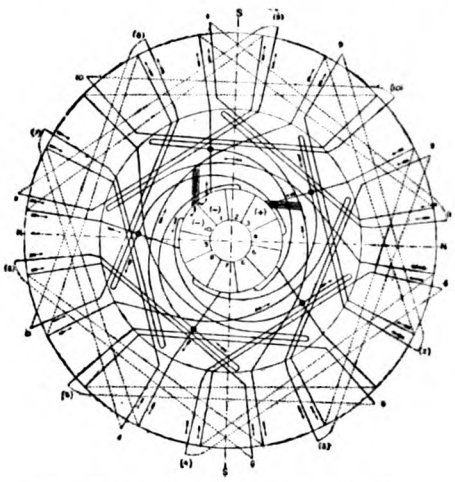

Fig. 24.—Alioth Winding, two parallels.

comparison has not always been in favour of British engineering. The Exposition of 1889 will have advanced electrical engineering amongst us in no little measure if the lessons there learnt are duly appreciated. Englishmen, and Scotchmen, too,

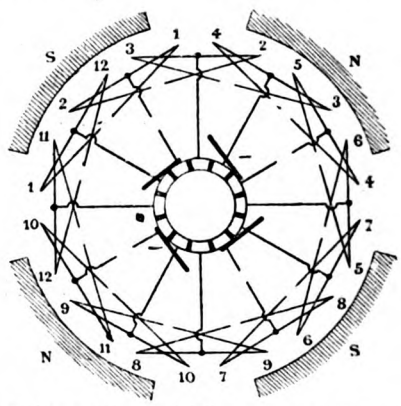

Fig. 25.—End View of four-pole Thury Drum Armature Winding.

but in a lesser degree, are apt to gauge things exclusively by the limits of their particular horizon. This sort of thing did well enough in the early part of this century, when engineering was almost confined to Great Britain: but things have changed

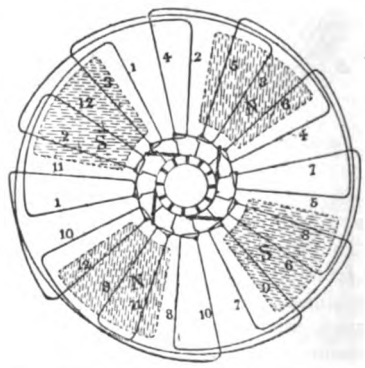

Fig. 26.—New Edison Disc Winding.

since then. The spread of technical education, the large number of industrial exhibitions, as well as the ordinary march of events, have contributed to the dissemination of knowledge, and the Continental firms are now formidable opponents in most of the branches of civil, mechanical, and electrical engineering.

THE GOOLDEN-EVERSHED OHMMETER.

We recently had an opportunity of inspecting a new apparatus that is being introduced by Messrs. W. T. Goolden and Co., for the measurement of "insulation resistances," and we must congratulate Mr. Evershed, and this firm, on being able to bring out an inexpensive instrument that is portable and apparently well suited to its purpose. The idea of an ohmmeter, if we remember rightly, is due to Profs. Ayrton and Perry; but it has been left to Mr. Evershed to carry out its construction in a manner having the necessary practical and commercial qualities. The value of insulation tests made with a few cells has never been considered great—dynamo makers, in particular, being fully aware of the lowering effect which even the application of very ordinary pressures has upon the properties of insulators. The difficulty, however, of making tests outside the factory with high E.M.F.s had stood in the way of reliable main and house-wire tests. But now that to a portable ohm or megohm-meter we have the addition of a portable 100 or 120-volt generator, we may look for better things.

In Fig. 1 is shown the complete apparatus, consisting of a direct-reading ohmmeter, graduated with a range from 10,000 ohms to five megohms, with an open scale and distinct figures, and a portable magneto-generator of special construction, enabling 100 to 120 volts to be obtained by turning the handle at the moderate speed of about 120 revolutions per minute. All that is necessary to measure the insulation resistance of any circuit is to couple the wires to be measured to the terminals, turn the handle, and the needle at once points to the number of thousand ohms or megohms representing the insulation resistance.

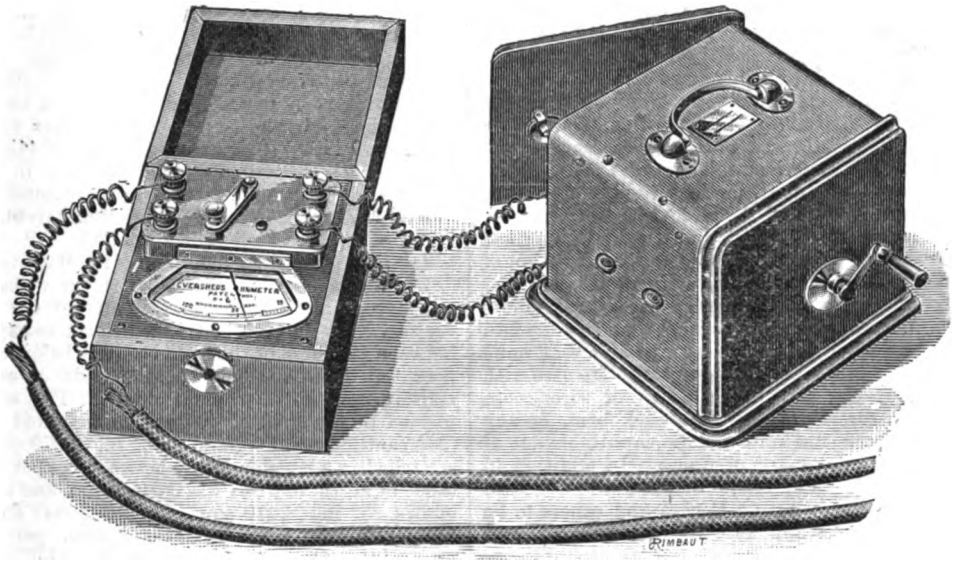

FIG. 1.—Ohmmeter and Mechanical Generator.

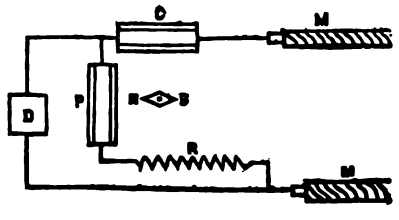

FIG. 2.—Connections of Ammeter and Generator.

In Fig. 2 the connections of the ohmmeter and generator are shown diagrammatically. The generator D and current coil C are connected in series with the mains M M, the insulation resistance of which is to be measured. The pressure coil P, with a large resistance, R, is arranged as a shunt on the generator. The direction of the resultant magnetic field of the current and pressure coils depends on the ratio of the currents in them, and as the current in the former is $\frac{E}{r+x}$, where r is resistance of current coil, and x the insulation resistance of the mains; and the current in the pressure coil is simply $\frac{E}{R}$, where R is the total resistance of the pressure coil and its series resistance, we see that the direction of the resultant field depends only on $\frac{r+x}{R}$. The needle system is either astatic or placed in a field reduced nearly to zero by means of a neutralising magnet, so the position of the needle N.S. depends on $\frac{r+x}{R}$. The term r is eliminated in the process of calibration, each division corresponding to $(r+x)$, ohms being marked as x ohms. The position of the needle depends only, therefore, on the ratio $\frac{x}{R}$. As the current coil is traversed merely by the leakage current, its field is very weak, so that it has to be made of several thousand turns and the needle brought as close as possible to it. The ohmmeters usually made to read from five megohms down to 100,000 are ohms on one scale, and the current coil is provided with one or two shunts to continue the range down to 10,000 or 1,000 ohms.

In addition to their use as *ohmmeters*, these sets of testing apparatus completely dispense with the lineman's detector and battery. The generator alone may be most conveniently used for continuity tests during the wiring of houses, &c., by keeping it connected to the main leads; and while it is being driven at a moderate speed, every pair of single-light leads is tested by making contact and noting by the sparking whether the circuit is intact. The whole process is exceedingly quick and certain. A short-circuit at any point of the ramification can also be detected by the severe drag on the generator handle, and by the violent sparking at the commutator.

The whole apparatus is compact, well constructed, and neatly finished off, and should prove an indispensable adjunct to the equipment of anyone engaged in the practical testing of insulation resistances.

ON THE HEATING OF CONDUCTORS BY ELECTRIC CURRENTS.*

BY A. E. KENNELLY.

Although the best economical dimensions of a conductor employed to transmit power are determined by Sir William Thomson's law that that portion of the cost rate depending directly upon the cross-sectional area of the conductor should equal the average cost rate of the power it absorbs in its duty, and although, at the existing prices of copper and of power, such a conductor must be very heavily loaded to acquire a dangerously high temperature, yet not only may its limits of safe capacity be strained by occasional pressure, but it is well known that in practice economy is not the only factor that determines a conductor's size, since the necessity, for example, of maintaining a constant difference of potential over an entire network of electric light mains under wide variations of load may sometimes clash with the conditions of economy in their transmission or even of safety in their temperatures.

Notwithstanding the consequent importance of a complete knowledge of the safe carrying capacity in conductors under all practical conditions of service, the subject has not, apparently, received the attention it deserves, and the simplicity of the law which determines the generation of heat in an active conductor seems to have led the complexity of the laws governing the dissipation of that heat, and thus limiting temperature, to have escaped the full notice of practical men. The most important published contributions to the subject appear in two Papers, one by Mr. W. H. Preece, to the Royal Society (see *The Electrician*, February 17 and 24, and April 27, 1888), and the other by Prof. G. Forbes, to the London Institution of Electrical Engineers (see *The Electrician*, April 5, 1884). The former deals principally, however, with the fusing currents of wires for different metals and diameters, while the latter is almost exclusively devoted to the theoretical treatment of the subject. Had the experimental data of Prof. Forbes' Paper been as exhaustive as its mathematical investigation was complete, there would probably have been little left to add or amend from an engineering point of view; but the vital numerical coefficients it adopts are taken from experiments on the emission of heat, which, however accurate and valuable in themselves, are not fairly applicable to the conditions of conducting wires, and which, in their published form, tend rather to conceal than to elucidate the principles underlying the subject. The fact remains that none of the existing text-books or tables up to the present date give with any pretension to accuracy the carrying capacity of wires consistent with safe temperatures, in clearly tabulated form, or any clear conception of the variation the limit undergoes with change of environment—empanelled, free, or out of doors. In addition to this, the rule of the British Board of Trade for installations within doors has been pointed out by Professor Forbes and others to be very uneconomical for small wires, and actually unsafe for wires of a certain, though perhaps unusual, diameter.

To determine some of these unknown quantities, and particularly with a view to obtaining the necessary data for the fire insurance offices, the Edison Electric Light Company, of New York, recently instituted a series of experiments at the laboratory of Mr. T. A. Edison, in Orange, N.J., aud with their permission the results obtained are now published. Not only have satisfactory general rules been arrived at for the safe carrying capacity of conductors, but the numerical coefficients in the formulæ given by Forbes have been determined with a fair practical degree of accuracy, while the field has been opened for further useful investigation.

The experiments were made on conductors under three different conditions:

1. With insulated copper wires encased in wooden panelling to represent house wires.
2. With copper wires, both bare and covered, suspended on poles in the open air to represent overhead service.
3. With copper wires and strips suspended across a room to represent the conductors in an electric light station, and also to form a connecting link between the two previous conditions.

The elevation of temperature produced in the wires (whose conductivity varied from 97 to 101† per cent.) was in every case determined from the increase of their resistance observed after the experimental current had been passed through them sufficiently long to practically attain a limiting permanent temperature. This period of time was found to be about ten minutes with the panelled, and some two minutes with the suspended wires. With the former, a steady increase of resistance, which, according to theory, would continue for all time, could be noticed for as much as 30 minutes, but it was estimated that the temperature elevation reached in 10 minutes was 97 per cent. of its full ultimate value, and the greater accuracy attained by longer intervals of flow would not have repaid greater loss of time, especially as the quality of the wooden panel, its thickness, form and position, would practically involve commensurate variation in results.

It has been sometimes believed that the temperature elevation computed from the rise of resistance would be somewhat in defect, owing to the gradient of temperature from the centre to the circumference, and the cooling of the external surface. Analysis shows, however, that this source of error is too trivial to be taken into account, for if θ be the difference of temperature in degrees Centigrade maintained in the permanent state between the axis of a wire and its exterior, then it will be found that

$$\theta = \frac{\rho}{J\,K}\left(\frac{C}{O}\right)^2;$$

where ρ is the resistivity of the wire,
C is the current it carries,
O is its circumference,
J is Joule's equivalent, or 42 megalergs,
K is the thermal conductivity of the metal,
all being expressed in absolute measure.

For a copper wire of one centimetre in circumference, carrying 100 amperes, with $\rho = 2{,}000$ and $K = 1{\cdot}1$, $\theta = \frac{1}{220}$ of 1°C.

Empanelled Wires.

Two 20-foot lengths of pine panelling were made, and in all the tests these panels rested with their broad bases on the wooden floor of the testing-room. In the smaller size, 12 wires, ranging from 0·0185in. (0·047 centimetre) to 0·119in. (0·302 centimetre) diameter, were successively tested, one side only of the panel being occupied at one time. In the larger size, 12 larger wires were tested, ranging from 0·119in. (0·302 centimetre) to 0·445in. (1·131 centimetres) diameter, generally two at one time, one in each compartment, so that the observations may be said to extend to diameters of nearly half an inch, or from wires whose resistance per metre varied from 0·019 ohm to 245 microhms at 0°C. All the resistances in the tests are expressed in legal ohms (106·0 centimetres).

The increase in the resistance of the wires due to their heating was determined in the cases of all but the very smallest by that very accurate null method, in which the variable potential difference between the ends of the tested wire is balanced against the constant potential difference between the ends of an invariable platinoid resistance in the same main circuit. This standard resistance was formed by the grid of 40 parallel platinoid wires, each eight feet (244 centimetres) long and 0·031 in. (0·079 centimetre) in diameter, stretched in a wooden frame between copper rods. The joint resistance of all these wires was 0·0499 ohm, and their large total surface of 374 sq. in. (2,410 square centimetres) and small coefficient of temperature variation (0·021 per cent. per degree C.) effectually maintained the resistance constant within at least 0·1 per cent. under all current strengths employed, especially as with the stronger currents the grid was connected with its two halves in multiple by letting the current enter at a third copper rod in the centre and divide among the forty wires on each side, the total resistance in this condition being 0·0121 ohm. To balance the potential differences supplied by the wire and the grid, a dead-beat differential mirror galvanometer was employed. It was carefully adjusted for differential perfection, until five volts connected with its coils in opposition series produced a barely perceptible deflection. The resistances and balance of the coils (about 2,700 ohms each) were observed before and after each test. During the observations one of these coils was connected with the panelled wire, and the other in opposition with the platinoid grid. The initial difference between the opposed currents thus acting on the needle when the first feeble current was sent through the main circuit, was reduced to vanishing point by inserting resistance in the circuit of preponderating influence. Under these conditions the resistance of the wire became determined, and its terminal potential difference exactly balanced on the galvanometer that from the grid. As the current in the main circuit was successively increased this balance became upset by the corresponding rise of temperature, resistance, and terminal P D of the wire, necessitating readjustment of the inserted resistance, while the extent of this readjustment supplied all the data for the calculation of the change. This method was found to be very sensitive, and allowed the rise of temperature to be observed in a convenient manner for estimating the approach to limiting permanent state, while all slight variations of the dynamo-testing current were eliminated, since their effect was equal and opposite on the galvanometer circuits. The temperature elevation was carried up to 100°C. except in the case of the largest wires. The strength of the current passing in the main circuit through wire and grid from the laboratory 110-volt dynamo was adjusted by platinoid resistances for the feebler currents, by banks of Edison lamps for the stronger, and by a set of overhead wires for the strongest of all, the limit reached being 300 amperes. It was

* Abstract of Report read before the Edison Convention at Niagara Falls, August, 1889.

† Samples of copper offering a conductivity of as much as 104 per cent. of the original Mathiessen standard are stated to have been produced within the last few years, showing that the value of the standard needs revision under improved forms of chemical and mechanical treatment.

Digitized by Google

measured by means of a potentiometer connected with the grid, and also by at least one ammeter or dynamometer in the main circuit, whose readings were taken as a check upon the former. About one reading of the current per minute was observed, and the mean taken as that of the average current flowing during the period. The potentiometer employed its own working battery, mirror galvanometer and Clark standard cell.

The accompanying diagram (Fig. 1) shows the curves obtained by freely connecting the plotted observations resulting from the whole series of panel measurements. The ordinates represent the temperature elevations and the abscissæ are the current strengths to which those temperature elevations are due. Of the three connected variables, diameter, current strength and rise of temperature, this figure most clearly indicates the relation between temperature and current, while the influence of diameter may be deferred for the moment. It is seen that, generally speaking, the temperature elevation varies as the square of the current strength for any given wire. This would be, perhaps, rigorously true if the resistance of the wire did not increase with temperature, if the conductivity of the panel remained constant, if the space between the wire and the panel walls were filled with solid material, and finally, if the exterior surface of the panel were maintained at the temperature of surrounding bodies. Under existing conditions the wire generates heat, owing to its rising resistance, faster than the square of the current; while, on the other hand, radiation and convection from the external surface are more than proportionally active as the temperature rises, the two deviations thus counteracting to some extent. So that, while the above law cannot be expected to apply accurately, the observations show the departures from it are not so great as to make the rule practically unserviceable. For diameters below 0·10in. (0·25 centimetre) the temperature elevation appears to have risen more slowly than the square of the current, while for diameters above 0·30in. (0·76 centimetre) the opposite tendency is shown.

On plotting the results of Fig. 1 in such a manner as to elicit the dependence of temperature elevation on diameter alone for constant-current strengths, the curves so obtained have not been identified with any simple algebraic law; in fact, the conditions are of so complex a nature as to afford little hope of a simple, yet rigorous, law applying. The loss of heat is taking place, first, by conduction through the insulating covering of the wire, then by conduction, convection, and radiation through the enclosed air space; next by conduction through the woodwork; and finally, into the floor or wall to which the panel is fixed, while radiation and convection carry off the heat from the free surface exposed to the air. Even under the simplest conditions that can be imposed in imagination upon the panel, such as cylindrical form with free access of air all round, and a tight fit upon the wire at the axis, the law of temperature increase with diameter for constant currents would involve the ratio of the panel diameter to the wire's diameter logarithmically, and the various dis-symmetrical but practical conditions can only serve to make the law more complicated. In the absence then of any simple rigorous law, it becomes necessary to select some particular temperature elevation as the safe limit which a wire can be allowed to reach under ordinary conditions, and then to find the best empirical rule which shall approximate as nearly as may be needed to the curve of experimental results.

The rule recommended by the Committee of the London Institution of Electrical Engineers for the prevention of fire risks in electric lighting, as published last year, was that:—"The conductivity and sectional area of any conductor should be so proportioned to the work it has to do that if double the current proposed be sent through it the temperature of such conductor shall not exceed 150° F." With this rule as a guide, the only remaining question is the normal temperature of the wires from which the rise is assumed to take place. A cellar in winter time might have a temperature of 40° F. (4·5° C.), while near the ceiling of an artificially-warmed room the thermometer might reach 100° F. (38° C.) As it would be out of the question to design every wire in a house for the exact temperature it might normally possess at different portions of its length, a fair mean temperature must be selected from which all elevations can be reckoned. This mean temperature may be taken at 75° F. (24° C.). This being admitted, the rule above-mentioned requires that the temperature elevation of any wire shall not, with double the proposed current, exceed 75° F., *i.e.*, reach above 150° F. (41·7° C.), and it has been seen that this is, for practical purposes, equivalent to the statement that the proposed current shall not produce an elevation of one-fourth that amount (10·4° C.).

Fig. 2 shows the general results arranged for the purpose of directly indicating the observed dependence of current strength and diameter for any given temperature elevation. Taking for granted that the 10° C. elevation is that which prescribes the safety limit as above, then the empirical formula which shall best represent the 10deg. curve will form the rule by which the safe diameters of panelled wires may be determined. For the 10° C. curve itself it is difficult to find a simple equation, but for the broken line curve near it, — — —, which follows the current whose double raised the temperature 40° C., the equation: Limiting current in amperes = 560 (diameter of wire in inches) $^{3}/_{2}$, is seen to be closely applicable except for very small wires, the curve — · — · —, in conjunction, being the strict locus of this equation. This formula makes the small wires rather larger than experiment has shown they need be, but it will be seen that even then they are much smaller than the Board of Trade rule requires. The following are then the proposed formulæ for determining the limiting safe currents and diameters for insulated copper wires in wooden panels:—

$C = 560\ d^{\frac{3}{2}}$, if d be expressed in inches;
$= 0{\cdot}01775\ d^{\frac{3}{2}}$, if d ,, ,, mils;
$= 138\ d^{\frac{3}{2}}$, if d ,, ,, centimetres;
$= 4{\cdot}375\ d^{\frac{3}{2}}$, if d ,, ,, millimetres.

And reciprocally,

$d = 0{\cdot}0147\ C^{\frac{2}{3}}$, if d be expressed in inches;
$= 14{\cdot}7\ C^{\frac{2}{3}}$, if d ,, ,, mils;
$= 0{\cdot}0374\ C^{\frac{2}{3}}$, if d ,, ,, centimetres;
$= 0{\cdot}374\ C^{\frac{2}{3}}$, if d ,, ,, millimetres.

For ordinary purposes it is convenient to remember that when d is expressed in inches and C in amperes, $d = \frac{\sqrt[3]{C^2}}{70}$.

From these data we have the following table giving in inches and centimetres the diameter of insulated copper wire necessary for any specified current:

Amperes.	Minimum safe diameter of copper wire.		Circular mils per ampere.	Fall of potential in wire at full load.	
	Inches.	Cms.		Volts per foot.	Volts per metre.

DATA.—Insulated house wires carrying continuous currents, and encased in wooden panelling. Copper resistivity: 1·650 microhms @ 0°C. = 1·870 microhms @ 34°C. assumed temperature of full load. Conductivity allowed 98 per cent.

This table shows that whatever temperature elevation might be adopted as the safety limit, the principle of fixing upon the diameters of conductors by allowing a certain number of amperes to the square inch, or a certain number of circular mils to the ampere,

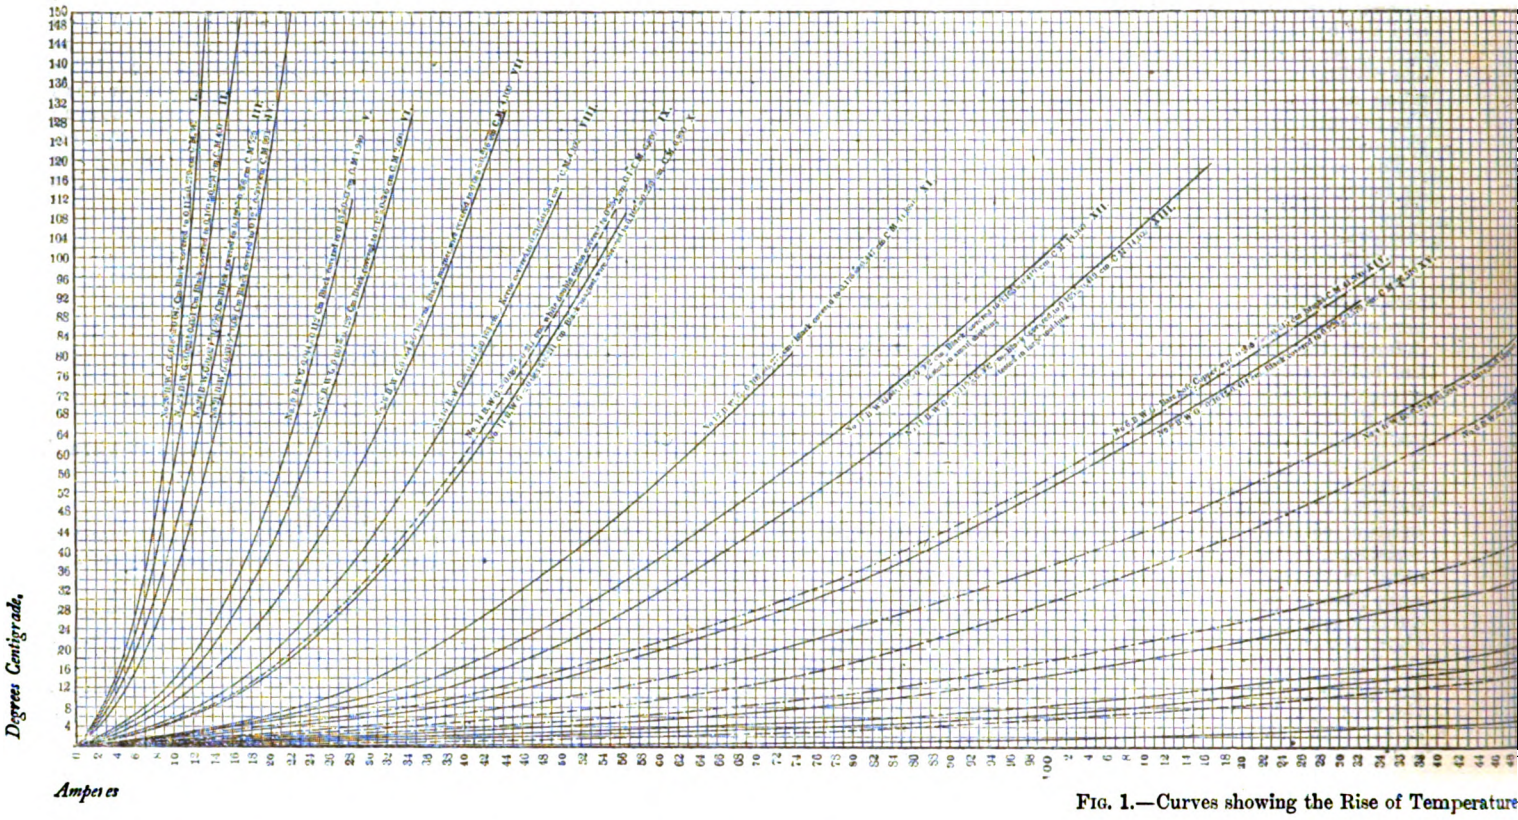

FIG. 1.—Curves showing the Rise of Temperature

can only be very imperfect unless a sliding scale be arranged. Thus the diameter of wire which coincides with the Board of Trade limit of 1,000 amperes per square inch is 0·504 inch for 200 amperes. at 1,000 amperes per square inch requires 508,000 circular mils, or a diameter of 0·713in., while the table indicates 0·800in. ; and, on the other hand, to carry 40 amperes the same rule calls for 0·225in., the table showing only 0·172in. to be necessary. For the same reason, when the space occupied by the wires is no object, there is always an economical limit to the size of the main in any house installation, for if the fall of potential permissible in them reduces their selection to pure considerations of safety, then it will always be more economical to subdivide the conductors for heavy currents. For example, if 500 amperes have to be carried at full load, the table indicates a main of 0·928 inches (2·36 centimetres) in diameter. But by taking two equal mains each, carrying 250 amperes, their diameters will be 0·585 in. (1·49 centimetres) and the weight of copper will be reduced rather more than 20 per cent. ; and in all cases, whenever 20 per cent. of the cost of copper necessary for one main will more than cover the expense of another insulating covering and panelling for the second wire, there being no independent objections, it will be economical to divide the conductor. This remark is, of course, not merely a deduction from the table, nor in any way implicated with the limiting temperatures on which it is based, but is founded on the fact that when a wire's diameter is

Diameter C'ms.

FIG. 2.—Curves representing the Dependence of the Rise of Temperature in Wires upon their Diameter.

According to the table, that rule would not be safe for wires above that diameter, while for wires beneath that diameter it would, in respect to safety, be very economical. Thus, to carry 400 amperes

Curves showing the rise of temperature in wires carrying currents and encased in wooden molding from measurements made at the Edison Laboratory 1889. The diameters of the wires are given in inches and in centimetres. Full lines indicate black covered wires and kerite, ———— white covered; and —— — —— bare wires. All of copper. The molding was altered between curves XII & XIII to admit larger conductors. Length of molding twenty feet.

s carrying Currents and encased in Wooden Moulding.

doubled, although it takes twice as strong a current to develop the same heat as before per unit volume, there will be four times as much total heat and only twice as much surface through which that heat has to find egress.

Referring to the general curve sheet, certain deductions may be made from it concerning the effect of the nature and thickness of insulating covering, and also the influence of the panel dimensions. The evidence is distinct that, with all the wires tested, and which had the usual thickness of insulating covering [about 0·050in. (0·13 centimetre) for the small and large wires, with about 0·035in. (0·09 centimetre) for the intermediate sizes], the effect of the insulation covering was to cool the wire. Thus, curves Nos. XIV., XVI., and XVIII. (Fig. 1) represent the observations on bare copper wires, and show that their temperature elevations were fully 30 per cent. in excess of that found in covered wires of equal diameter and load. Again, curve No. VIII. refers to a kerite wire whose coating was 0·073in. (0·185 centimetre) thick. Its temperature elevation is seen to have been about 30 per cent. lower than that obtained with a wire of the same diameter but only covered to a thickness of 0·011in. (0·028 centimetre), No. VII.

As regards the surface nature of the insulating material, curves Nos. IX. and X. represent the behaviour of two wires whose diameters and thickness of insulation were practically equal. No. IX. was double covered with white cotton; No. X. single covered with blackened cotton. All the ordinary insulated house wires were covered at the Edison Machine Works, Schenectady, N. Y., with cotton soaked in a special insulating liquid. The temperature elevation of the latter was about 4 per cent the lower, and while it is possible that this difference may have been due to the superior radiating power of the black coating, it is not sufficiently marked to be more than a possibility. Curves Nos. XII. and XIII. show the temperature elevations of the same length of wire first in the smaller panelling and then in the larger. In the latter case there is a cooling effect visible, amounting to 10 per cent.

The conclusion rests that while the exact temperature elevations of a panelled wire depends upon a variety of factors, it is capable of being fairly estimated from the average of a number of experiments under actual conditions, and care has been taken to obtain these measurements under as nearly practical conditions as possible. The mean conductivity of the wires was about 99 per cent.; that is to say, a mean resistivity of 1,640 absolute legal units. The temperature coefficient has been taken at $1+0{\cdot}00388\,t$, t being the elevation in degrees Centigrade. In applying the rule for safety limitation as given by the table, insulated wires are, of course, to be understood, and no particular thickness or quality of insulation need then be specified. For although extra thick insulating covering cools the wire, it would not be desirable to render it specially thick merely with that object in view. Also each wire should have its own groove, or, if several wires are in the same channel, the total area and surface of the woodwork should be correspondingly large. Finally, the panelling should be run as far as possible through places not exposed to an abnormally high temperature.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, December 13th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read, "Hydraulic Station and Machinery of the North London Railway, Poplar." By JOHN HALE, Stud.Inst.C.E.

MONDAY, December 16th.

LONDON INSTITUTION.

5 p.m. Lecture: "Lustre Decoration in Ceramic Art." By HENRY WALLIS.

SOCIETY OF ARTS.

8 p.m. CANTOR LECTURE I. 4. "Modern Developments of Bread-Making." By WILLIAM JAGO.

TUESDAY, December 17th.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture: "My Experiences in Cape Colony." By Prof. H. G. SEELEY.

WEDNESDAY, December 18th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read:—"Report of the Wind Force Committee on the Factor of the Kew Pattern Robinson Anemometer." Drawn up by W. H. DINES, B.A., F.R.Met.Soc. "On Testing Anemometers." By W. H. DINES, B.A., F.R.Met.Soc. "On the Rainfall of the Riviera." By G. J. SYMONS, F.R.S. "Report on the Phenological Observations for 1889." By EDWARD MAWLEY, F.R.Met.Soc.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. Ordinary Meeting. Paper to be read, "Percussive Rock Drilling Machinery." By R. BOLTON.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read, "London Sewage." By Sir ROBERT RAWLINSON, K.C.B.

THURSDAY, December 19th.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny.
Editorial, Publishing and Printing Offices:
No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.
Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

ELECTRICAL NOMENCLATURE.

We recently commented upon some portion of our correspondence which raised questions concerning the appropriate name and magnitude of the unit of self-induction. In returning again to the subject there are, however, some general questions in connection with the subject of electrical nomenclature which it may not be inappropriate to discuss. The nomenclature of every science, like a poet, is born and not made. It has to grow and develop by a process of evolution, and does not depend on arbitrary decrees. We remember that in some of his writings, Mr. HERBERT SPENCER has pointed out how the commonest actions of modern daily life, such as shaking hands or raising the hat in saluting, have been evolved from actions having very definite significations in the life of ruder times. The precise nomenclature of science develops in like evolutionary manner, and it is impossible to produce a sudden discontinuity in this process. In order that a term or word shall be assimilated uniformly and thoroughly into the usage of everyday life in technical matters, it is essential that it shall meet a general want which has made itself felt prior to the advent of the term. It does not, however, follow that the first attempts to build up the nomenclature of a science make more than an initial approach to naming that which requires to be named. In many cases names or terms primarily cover ignorance, and, in so far as they have only an appearance of knowledge, and are destitute of perfectly clear meaning, they may be a hindrance instead of an assistance at a further stage of knowledge. Prof. HUXLEY is reported to have once said that if he met with the word *polarity* in a book not having reference to physics, he read no more of it. We might instance such terms as *polarisation* and *catalytic action*, employed by some writers in physics and chemistry, as terms of a similar kind which cover great amounts of ignorance.

The first attempts to form the nomenclature of a science generally result in terms and words which suggest or contain too much hypothesis. In some respects the progress of science may be said to consist in making our words mean less and less—that is to say, depriving them of hypothesis and employing them to denote simply observed facts or

1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

ADDRESSES.

LAING, WHARTON, & DOWN, 82a, NEW BOND-STREET, LONDON, W., Electric Light Engineers & Contractors. Sole Operators for England of the Thomson-Houston system of Arc Lighting. Special Agents for the Edison-Swan Co.'s Incandescent Lamps and Apparatus. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting, Venetian Shades and Glass, Carbons, &c. Temporary lighting on any scale at short notice. Estimates free. Telephone No. 3602.

JULIUS SAX, Electrical Engineer and Electric Light CONTRACTOR, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.

Established 1855.

Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torpedo Apparatus.

Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works.

Call Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractor to H.M. Post Office and War Office.

Electric Lighting—Domestic and Public. Estimates Free on Application. Eight Prize Medals awarded.

Telephone No. 3848. Telegraphic Address: "*Sax—London.*"

WALTER T. GLOVER & CO., Electric Wire and Cable Makers, SALFORD, MANCHESTER. Works: Bridgewater-street, Broughton-road, Salford; Salford Electric Wire Works, Salford; Springfield-lane Cable Works, Salford. Established 1868. London Address, 10, Hatton-garden, E.C.; Telegram, "Phonoscope," London; Telephone No. 6691. Manchester—Telegram, "Walter Glover," Salford; Telephone No. 1187.

Specialities—Glover's patent covered Gutta Percha Wire for Leading-in, Tunnel, and Underground Work. Specially covered Iron and Copper Wire for Aerial Lines. Fancy covered single and Double Copper Wire (Paraffined) for Telephonic and Bell purposes. All classes of Silk and Cotton covered Wires for Instruments and Dynamo Machines, Glover's Patent Electric Light Leads and Cables for the various systems.

All descriptions of Covered Wire and Cables for Telegraphic, Telephonic, and Electrical Work, as supplied to the Post Office and the principal Railways, Electric Light, and Telephone Companies.

ADDRESSES.

PHILLIPS BROS., Electrical Wire Manufacturers, The Lea Telegraph Works, HACKNEY WICK, LONDON, E., late of Macintosh-lane, Homerton. Established 1870. Telephone No. 5422.

Specialities—Gutta Percha, India Rubber, Compound, Cotton, Silk, Flexible Cords, Telephone Wire, &c., &c. Multiple and other Wires. Special Wires for Dynamo Machines. Electric Light Leads, &c Patent Non-Inflammable Insulation for Incandescent and Arc Lighting and Dynamo Machines.

THE LONDON ELECTRIC WIRE COMPANY, ANCHOR WORKS, PLAYHOUSE-YARD, GOLDEN-LANE, LONDON, E.C. (Late of Wenlock-buildings, Ironmonger-row, E.C.)

Specialities—Covered Wires of all descriptions for Electrical Instruments, Dynamo Machines, Bell and House Work, &c. Fancy Paraffined Wires specially prepared for Telephone and other indoor connections.

JOSEPH BOURNE and SON. Works: DENBY POTTERY, near DERBY. London: 6, ST. PANCRAS STATION. Manufacturers of the well-known Stoneware Telegraphic Insulators and Battery Jars. Brown Stoneware. White Stoneware. Brown Porcelain. Porous Cells. Economy, strength, durability, and perfect insulation combined. Prize Medal, Paris Electrical Exhibition.

Makers of Mr. Slater Lewis's Patent Self-Binding Insulator.

J. G. STATTER and CO., Limited, Engineers, ALLIANCE ENGINEERING WORKS, WEST DRAYTON. London Offices, Prince's Mansion, 68, Victoria-street, Westminster S.W. Dynamos and Motors for all Purposes. Perfect Constant-Current System of Arc Lighting. Estimates free. Write for Lists.

LAURENCE, PARIS and SCOTT, Limited, Electrical ENGINEERS and CONTRACTORS, GOTHIC WORKS. KING-STREET, NORWICH. Dynamos, Motors, Automatic Cut-Outs, Back Current Cut-Outs, Excess Alarms, Multiple Switches, and Switch Boards. Complete Electric Lighting Plants. Central Station Plants. Estimates on Application.

PATERSON and COOPER, Electric Light and Power and Telephone Engineers. EUROPEAN WORKS, POWNALL ROAD, DALSTON (Near Haggerston Station). Contractors to H.M. Government, Leeds Corporation, &c.

Specialities—Phœnix Dynamos, Pilsen, Phœnix, and Clark-Bowman and J. F. Arc Lamps, Cardew's Voltmeter, Paterson's Electromagnet Am- and Voltmeter, Ayrton-Perry Am- and Voltmeters, Wallace Diamond Carbons, Switches, Safety Junctions, and Fittings for Arc and Incandescent Lighting. very definite ideas. It is not by any means an unworthy task to endeavour to shape with the utmost care the definitions and nomenclature of a science. Even in the case of the older sciences, like dynamics, great good results from a careful re-examination from time to time of the phrases and definitions and terms employed. A loose or inappropriate vocabulary is a great bar to the progress of discovery, and an inestimable boon is conferred on scientific workers by anyone who readjusts the vocabulary of a science so as to be more in accord with the facts. The great service rendered to electrical science by Dr. G. S. Ohm is known to every student. We have only to refer to the writings of the early investigators of galvanism and electro-magnetism to see how much they were fettered by the want of precision in nomenclature. To analyse any complex phenomenon like the production of an electric current into its simple constituent notions, and to affix to each idea or fact an appropriate name, is a work of time; and even when those who have thought most deeply on the subject have decided amongst themselves what will be the proper mode of naming and analysing these facts, it involves still greater delay before the general body of workers have been brought by education or training to view the phenomenon from the same point of view. The older chemists, brought up to regard the phenomenon of combustion from the point of view of the phlogiston theory, had considerable difficulty in assimilating the ideas and terms which LAVOISIER'S discovery of oxygen and his theory of combustion involved. It thus happens that different sections of scientific workers speak and think in terms or phrases which are dissimilar. The purely scientific worker adopts terms or phrases which have been suggested to his mind by experimental or mathematical analyses, having as their only object the disentanglement of the true from the false. The more practical or constructive worker, one whose work consists in applying known principles and facts in everyday life, requires a vocabulary which is more picturesque or suggestive than that adopted by the scientific worker. Electric pressure, as a term, is to the practical man more suggestive than electric potential; number of lines of magnetic force than magnetic induction, or surface integral of magnetic force, and magnetic resistance than magnetic permeability. The practical constructor and the scientific investigator have thus some difficulty in adapting their thoughts to one common language. The practical man is apt to take too simple a view of Nature. He dislikes complex ideas; and, provided a phrase is good enough for him, he does not see why his scientific brother should be always wanting to coin fresh words or new phrases. The investigator of first principles knows, however, that there can be no finality in our ideas of any phenomena of Nature. All conceptions of natural facts and effects, and of the interpretation to be put on them, are imperfect. At every stage of knowledge our views of the connection of phenomena are imperfect, and the language in which ideas about them are expressed requires continually to be re-modified.

In an enormously progressive science like electricity there is the greatest difficulty in bringing the vocabulary of the science into accordance with the most highly probable interpretation of the facts, and hence arises a continual need for readjustment and modifications. Meanwhile, the facts remain the same, and those whose contact with the science consists rather in applying the facts than in examining their connection and relation to other facts, are apt to be satisfied with modes of expressions which are very imperfect in themselves. A mode of viewing certain phenomena which seems consistently to explain, up to a certain point, the facts, may be rendered very misleading by the discovery of further facts. For instance, the phenomena of self-induction carry with them and suggest certain ideas in electrical science which are the analogues of those which arise in connection with the idea of inertia in mechanical science. Electric inertia becomes a phrase which is taken into use to express definite ideas. Additional light on the true mode of viewing the genesis of electric currents in conductors may reveal that the whole phenomenon is much more akin to the gradual propagation of heat through a poker which has one end stuck in the fire, and that to connect the idea of inertia and mechanical momentum too absolutely with the gradual rise or decay of electric currents may be to avert the mind from that which it is necessary to study to advance our knowledge of the whole matter. If, however, a practical man has once found that expressions or terms based on that mode of regarding electric phenomena which renders their connections clearer by the use of language based on an analogy with the motions of a heavy fluids—then, finding that up to this point he is helped by it, he is apt to cling to it with considerable tenacity. Hence there is a difficulty in reducing to one common language the ideas of those who have different levels of thought and practice. To a practical telegraphic engineer the propagation of an electric signal or current through a wire is a much simpler matter than it is to a mathematical physicist, and the words they use to express themselves about it are therefore different. The practical man is apt to regard a good deal of the scientist's verbiage as a "vain thing fondly invented," and as having no reality. The theorist knows that the very essence of further practical applications is a continual advance in exploring the inmost nature of elementary phenomena.

From time to time practical science enters new fields of enterprise, and encounters in so doing facts and effects of a novel nature. So it has been particularly in the employment of periodic electric currents in telephony and electric lighting. It is then that a necessity arises generally for re-casting the vocabulary with the object of obtaining more precision and directness of expression in dealing with the effects and quantities which have to be measured. We have a particular instance of this in the terms which have been lately defined by the authority of the British Association Electrical Standards Committee. The term *impedance* has been adopted in the case of periodic currents to express the ratio of the square root of the mean square of the electromotive force during the period to the corresponding function of the current strength. And these quantities are respectively to be called the *effective electromotive force* and the *effective current-strength*. They are practically the quantities which are measured by a hot-wire voltmeter and an electro-dynamometer. The term effective electromotive force has been employed by some writers, when dealing with periodic currents, to express the difference between the actual external electromotive force acting in the circuit and the counter-electromotive force due to induction. In this last use of the term, the actual current flowing is numerically determined by the quotient of the so-called effective electromotive force by the real resistance of the circuit.

This selection of terms is, as some of our correspondents have pointed out, by no means entirely free from objection. This only shows how difficult it is to construct the vocabulary of any of the more recent developments of scientific work in a way that will render it at once complete and uniformly acceptable. There is much to be said for or against any of the terms which have thus been authoritatively defined. Time alone will show how far this nomenclature will find general acceptance, but meanwhile the advantages of a uniform mode of expression amongst writers and speakers is so great as to make it worth while to secure this, even if the terms and phrases are not destined to be absolutely permanent.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

The annual general meeting of the Institution of Electrical Engineers was held last night at the Institute of Civil Engineers, Great George-street, Westminster, when the undermentioned officers and Council for the ensuing year were elected :—

Officers and Council for 1890.

President.

J. Hopkinson, M.A., D.Sc., F.R.S.

Vice-Presidents.

William Crookes, F.R.S. | Alexander Siemens.
Prof. W. E. Ayrton, F.R.S. | R. E. Crompton, M.Inst.C.E.

Members of Council remaining in Office.

Major Philip Cardew, R.E. | Gisbert Kapp, Assoc.M.Inst.C.E.
W. Lant Carpenter, B.A., B.Sc. | Prof. John Perry, M.E., D.Sc., F.R.S.
Sir James Douglass, F.R.S. | Sir David Salomons, Bart., M.A.
Sir Douglas Galton, K.C.B., D.C.L., LL.D., F.R.S. | Prof. Silvanus D. Thompson, B.A., D.Sc., F.R.A.S.

New Members of Council.

Sir James Anderson. | Sir Henry C. Mance, C.I.E., M.Inst.C.E.
Sir Albert J. Leppoc Cappel, K.C.I.E. | Colonel R. Raynsford Jackson.

Associate Members of Council.

Augustus Eden. | Francis H. Nalder.
Sidney Sharp.

Hon. Treasurer.

Edward Graves.

Hon. Auditors.

Frederick C. Danvers, India Office, S.W. ; Augustus Stroh.

Hon. Solicitors.

Messrs. Wilson, Bristows, and Carpmael, 2, Copthall Buildings, E.C.

Bankers.

Messrs. Cocks, Biddulph, and Co., 43, Charing Cross, S.W.

Secretary and Editor of the Journal.

F. H. Webb.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"Electrical Engineering in America."*

BY G. L. ADDENBROOKE, ASSOCIATE.

(Continued from page 122.)

Underground Work.

Turning now from this branch of the subject to underground work, I must confess that I had a good deal of difficulty in getting really accurate and reliable information on this subject—at any rate, of a comparative character. The Edison Company have, of course, buried their wires all along, and their three conductors enclosed in an iron tube, run solid, with insulating material inside, are well known. As far as I could ascertain, the various systems of conduits have not proved very successful so far, and, since the proof of the pudding is in the eating, the fact that the Subway Company in New York are, I believe, laying down iron pipes entirely—at least, they were in every place I saw work going on—points to this conclusion.

The system of construction for underground work at present being carried out in New York is as follows :—Manholes at convenient distances are made in the roadway—not, as a rule, in the pavement, but just on the rise of the road, and clear of the gutter. These manholes are circular, and are covered by a heavy iron lid. Below the manhole is a bell-shaped pit eight or nine feet deep, and bricked round, and of sufficient size at the bottom for a couple of men to stand fairly comfortably to work. Iron pipes, such as are used for water or gas, are laid in the ground from one manhole to the next. I understand that each electric company will, as a rule, have a separate pipe, so that if there are several companies running along the street, they will each require a separate line of piping opening into the manhole. There will, therefore, often be several pipes entering at each side of the manhole. These pipes enter the manhole at such a height as, roughly, to come between the hips and breast of a man standing on the bottom—at a height, in fact, to bring them in a fairly convenient position for working. The cables are drawn through the iron pipes in the ordinary way. Branches are taken from the manholes under the roadway and pavement to any house between the manholes requiring current. As regards the class of cable which is being largely laid down in these conduits, the conductor consists of seven strands of No. 16 copper. These are insulated by a layer of a hard but somewhat flexible material, containing, I believe, some rubber in conjunction with other materials, but the complete material is cheaper than rubber used alone. The thickness of this material surrounding the conductors is one-twelfth of an inch. It somewhat resembles ebonite, and is of a consistency to stand rough usage and hard wear. It will be interesting to see how it lasts in practice. I must say it seems to me a very suitable material for the purpose for which it is intended ; and, as far as insulating qualities go, I was able to see the record of tests of a good deal that has been laid, and they were excellent, going up to several thousands of megohms per mile. The insulating material is covered with a lead pipe about one-sixteenth of an inch thick, and containing, I believe, a percentage of tin. These lead-covered cables are usually jointed at each manhole, and a little slack left on them there. The jointing is done by a special system, and when it is complete electrically the two lead tubes are drawn together over a small bit of brass tube, which protects the point of junction ; they are then "wiped" together with a hot iron like an ordinary plumber's joint. No doubt this work is heavy and expensive, but it looks as if it should last when once put down.

Internal Work.

Coming now for a moment to the internal work in buildings, most of what I saw had a rough, temporary look about it, evidently being put up as cheaply as possible. I do not say that no good, solid work is done, but the proportion of it to the remainder is, I fancy, a good deal smaller than in this country. Gas-fittings are freely utilised, and I think I am correct in stating that in the arrangement of lights the gas-fitting way of managing things is adhered to much more closely than in this country, where we have rather tried to avoid imitating the ordinary ways of arranging gas lights.

Turning aside for a moment, it appears to me that one of the great wants all over the world now is, if I may so term it, a "science of illumination." Up to and as far as *providing* light we are exceedingly scientific. But in *utilising* it when we have got it, we proceed in an elementary and haphazard manner. Mr. Preece has, I know, from the first paid a great deal of attention to this point, and appreciated its value. It seems to me that it would really be of great practical benefit if a Committee of this Institution, or some other responsible body, would accumulate some accurate and authoritative data on the subject. When once started properly, these data would increase of themselves, and would soon form a guide which would be exceedingly useful in drawing up specifications and arranging to the best advantage the lighting of either open spaces, public buildings, or private houses. We all have our own indefinite notions on the subject as the result of experience, but if they could only be put into definite shape—and I think the subject does admit of being put into definite shape—it would, I feel sure, be a great advantage.

Of course there are innumerable patterns of switches and cut-outs and fittings in America, as here, but none came to my notice showing any very brilliant conception in design. Lamp sockets and fittings are generally somewhat larger and clumsier than with us. The chief difference I noticed was that a switch is almost invariably included in each lamp socket. Americans, as a rule, do not go to the same amount of trouble and expense that is general here to fix switches in handy places near doors. If you want the light on or off, you turn it on or off at the burner as you would do gas.

Central Stations.

Coming now to central stations, those I went over were the new Arc Light Station in San Francisco, the Edison Station in Chicago, the Westinghouse Station in Pittsburg, and the Thomson-Houston Station in New York ; and I may add that since my return to London I have had an opportunity of going carefully over the new Westinghouse Station in Sardinia-street, Lincoln's Inn Fields, the plant in which is entirely of American manufacture and pattern, and arranged in the American manner. I might easily have seen many more stations—in some cases, perhaps, larger and better arranged than those I did see. But those I did see are, I think, all typical of the latest American work, and all were in the process of making large additions to their plant, so that they were quite up to date.

The station in San Francisco is near the railway station. It is a large brick building, erected entirely for its present purpose, about 250ft. long by 80ft. broad, with a ground and two upper floors, and has been finished about eight months. It is intended to provide accommodation for about 2,000 arc lights when filled up. At present it is furnishing current for about 600. It is arranged in the usual—I was going to say invariable—American plan of placing the engines and boilers on the ground floor, and arranging the dynamos, switch-boards, and electrical portion of the station on the first floor. In this instance the second floor is used as a storehouse, and for

* Paper read before the Institution of Electrical Engineers, November 28, 1889.

Digitized by Google

general purposes. The boiler-house forms one end of the building, and there was nothing above it. It is arranged for two lines of boilers, one on each side, one side only being filled up at present. They face towards the centre of the building, with a large space between for coals and general working purposes. The boilers were of the well-known water-tube pattern. This type, varied slightly in detail by each maker, seems to be in general use everywhere in the States. From the boilers the steam is led to a 650 horse-power single cylinder Corliss engine, which, by rope gearing, drives a single line of countershafting. I must say I was surprised to find that, in a new station so large as this, and one in which expense evidently had not been spared, the engine was neither compound nor condensing, particularly as there was water within a moderate distance. There was only this one engine in the station, driving all the dynamos, though space was provided for three more as the amount of lighting increased. The working of the station was therefore dependent on the single engine and line of shafting keeping in good order. The engine drove this line of countershafting, as I have said, the loose pulleys being on the shafting. At the stations I visited, where countershafting was in use, I was struck with the care and completeness with which means were provided for adjusting the plummer blocks and bearings in any direction. The general idea was somewhat as follows:—The plummer block, or upright, stood in a cast-iron shoe with a flat planed bottom, through which the holding-down bolts projected. The holes for the holding-down bolts in the plummer block were bored large so as to permit a certain movement in the block. The edges of the cast-iron shoe were turned up all round, and through these edges projected screw-bolts, the points of which touched the plummer block. By loosening, then, the holding-down bolts at any time, and screwing or unscrewing the screw bolts as required, the block could be slewed slightly or adjusted to line with the greatest nicety and ease. Besides this, the under bearing worked in guides, being kept in its place by a strong screw projecting up from underneath. By working on this screw, and on the cap of the upper bearing, the height of the bearing could, of course, be adjusted with great exactness. With these means the brasses are also quickly and easily replaced; while, if they get warm when the shaft is running, the bottom bearing can be slacked down. The Thomson-Houston Company, in New York, told me they did this, and their dynamos are on the same floor as the line of shafting. It is, of course, a still simpler and safer matter to do this when the dynamos are situated almost right above the shafting, as is the general practice in American stations. Leather belting of the ordinary description was in use, except for driving, where ropes are used, as I have mentioned. I found leather belting employed at each of the stations I visited. These long lines of countershafting must, of course, be wasteful of power; still, it is worth pointing out that such shafting runs under the best conditions when doing work right overhead, since both the dead strain and the running strain on the belts to the dynamos tend to lift the line of countershafting, which, therefore, if the weight is properly adjusted, must run very lightly in its bearings. The method of driving from underneath is also economical in belting, since the weight of the belt hanging on the dynamo-pulley causes it to have a good grip, and permits of a short length being used. The belts pass up to the dynamos through holes in the floor, the holes being elongated to permit the belt being tightened, if necessary, by screwing the dynamo along on its bed rails. In each of the stations I visited in America the upper floor carrying the dynamos was entirely of wood, strongly made, and supported from underneath at intervals by stout wooden uprights, but still of wood. The weight of the floor in the San Francisco station is entirely supported by the wooden uprights, being only steadied at the sides. I was informed at the old station in San Francisco, worked by same Company, and which, I understood, was supplying about 1,200 arc lights, a good deal of trouble was experienced from the floor, which was fixed to the walls, and which, vibrating with the motion of the machinery, shook the brickwork. I found the vibration on these wooden floors less than I anticipated, considering the amount of machinery on them; but, of course, the motion of a good dynamo is very even, and if the joints on the belt are neatly made there is no jerking. In this San Francisco station all the machines were Brush 60-lighters. From 50 to 60 lights in series on one circuit seems to be about the general rule for lighting in America when any number of lights is required. As all the machines are run from the same countershafting, and at the same speed, whatever work they may be doing, it is necessary to provide an automatic regulator to adjust the current through the field-magnets for each machine when doing less than its normal output. On the other hand, if the circuit is a very long one—and I was told some of the circuits at San Francisco are as much as 13 or 14 miles—the number of lamps on the circuit must be reduced to compensate for the extra resistance. These Brush dynamos were all mounted on short iron columns about 9 inches high, so that they were lifted entirely from the floor. I was told that this arrangement was found very handy for keeping the machines clear and free from dirt, and for inspecting them. I did not notice much difference between the machines and those turned out by our friends on this side of the water, and the style of the workmanship seemed to be about the same. A light overhead trolley, with lifting gear, ran overhead so that it could quickly be brought over any machine, and I was informed that should a machine go wrong, they could replace an armature in half-an-hour. In the older station in San Francisco a large number of Thomson-Houston machines are used, but Brush machines only are employed in the new station, as they find the Brush armature is more easily replaced, and is so much the easier of the two to repair if anything goes wrong. It is worthy of note in this connection that the latest advices from America inform us that the Thomson-Houston Company have bought the Brush Works at Cleveland, Ohio, and therefore presumably the Thomson-Houston Company will in the future control this interest as well as their own. From the dynamos the mains are led to a long narrow shelf, where are fixed the resistances and indicating instruments for each machine. The mains next proceed to the switch-board, which is of the plug pattern—brass plugs with boxwood handles united by a flexible insulated cord. All the flooring being of wood, as it is in each of the stations I saw, and being kept clean and dry, the risk of getting a bad shock is not great, except by shunting the current through oneself, or getting in series with a main, which are not ordinary accidents. At San Francisco the motor business is steadily increasing, and forms a welcome addition to the revenue of the station, without a very great additional expenditure.

I will now go on to the Edison Station in Chicago. There is no necessity to describe it at length, as the plans on which Edison stations are constructed have been published over and over again. The boilers, which are situated on the ground floor, are of the water-tube pattern—Heine arrangement. In this pattern, which seems to be a good deal used, the tubes are much more nearly horizontal than in the well-known Babcock and Wilcox type. All the tubes come into a large flat box at each end, and there are small manholes in the boxes opposite the ends of the tubes, for getting at them. These flat boxes are prevented from expanding with the pressure by tubular stays, which pass right through them, and are expanded in their places. These small tubes serve as blow-holes for directing a jet of steam on the upper side of the tubes to clear them of ashes. They are kept plugged up with a stopper, under ordinary circumstances, to prevent the gases coming through. These boilers had a damper projecting downwards in the furnace opening, for directing the draught over the surface of the coals when firing, to cause more complete combustion and prevent smoke. This damper may have been of some use for the purpose, but it certainly made it a difficult operation to fire properly. The engines were also in the basement, in the next room to the boilers. They were of the ordinary Armington-Sims pattern, single cylinder, and neither compound nor condensing. There was one to each dynamo, the dynamos being situated overhead on the floor above. The dynamos were of the ordinary Edison pattern, for, I think, 1,500 lights each. Everything was very neatly arranged in the dynamo room, the current being conveyed about by large copper bars. The walls were simply lined with resistances and indicators for the different circuits. In fact, the place gave one rather the impression of a wholesale clock store, though the attendant informed me they did not have much difficulty in keeping their resistances properly adjusted. All the mains are underground, on the three-wire system. Indeed, there is a good deal of underground work in Chicago, the Telephone Company also having a large number of cables buried.

(To be continued.)

THE PHYSICAL SOCIETY.

At the meeting of this Society, held on the 5th inst., Mr. S. Bidwell read a Paper on

"The Electrification of a Steam-Jet,"

illustrated by some beautiful and striking experiments. The jet was obtained from a small boiler, formed out of a tin canister, into the neck of which a cork was fitted, and this cork was traversed by a tube bent at right angles, and terminating in a nozzle. The object of bending the tube in this manner is to avoid having the flame used for boiling the water in the boiler immediately under the steam-jet, as the effect would then be to dissipate its charge of electricity. It is desirable that the glass tube should be as free from water as possible, and therefore it should be of comparatively large diameter. The tube employed in the experiments shown to the Society was $\frac{5}{16}$ths of an inch in diameter, and the nozzle at its extremity $\frac{1}{16}$th of an inch in diameter. Some four ounces of water were introduced into the small boiler, and heated until a strong but steady steam-jet was seen to issue from the nozzle (if the ebullition is too violent the water thrown up into the tube will produce unsteadiness); the image of the steam-jet was then thrown upon a screen by means of a projecting lantern,

Digitized by Google

and was seen to be of feeble intensity and of a neutral colour, being in fact nearly transparent, and appearing to exert little or no selective absorption upon the beam of light transmitted through it. A small bundle of needles in connection with one of the terminals of an influence machine was then brought near to the base of the jet, and the machine was slowly worked. The image of the jet instantly became dark and dense, and assumed a marked orange-brown tint, but instantly returned to its original condition when the electrified points were removed or earth-connected. It is not necessary for the points to be directed to the origin of the jet, as they are nearly as effective when placed in the steam at a distance of a foot from the nozzle, the whole of the steam-jet, from the nozzle upwards, being acted upon just as before. If a ball is used instead of a point, a similar result is obtained when the ball is actually within the jet, but not otherwise. Similar results may be obtained by directing the jet upon an electrified metal disc, which may be at a considerable distance from the nozzle. The author stated that he had examined the absorption spectrum of the steam-jet, and had found that, when unelectrified, the jet had very little action upon the spectrum, its total effect being merely to slightly diminish the brightness of the latter, the diminution appearing to be of equal intensity throughout, though he thought it possible that the violet might be dimmed slightly more than the other colours. Electrification was found to cause a total disappearance of the violet, and, at the same time, the luminosity of the blue, and the more refrangible part of the green, was decidedly diminished. The orange and red did not appear to be affected.

The author concludes from these observations that the effect of electrification is to cause an increase in the size of the water particles contained in the steam-jet. When the jet is unelectrified, most of these particles are small compared with the wave-length of light, but when electrified, their diameter may be something like $\frac{1}{5000}$th of an inch. It seems natural to suppose that the phenomenon was analogous to an experimental result obtained by Lord Rayleigh, in which a stream of water issuing almost vertically from a small orifice was found to break up into small drops at a certain distance above the orifice: and while, under ordinary circumstances, these drops collide with one another and become scattered over a considerable space; when an electrified body, such as a rubbed stick of sealing-wax, is brought near the point at which discontinuity begins, the drops no longer rebound, but coalesce, and the entire stream of water, both ascending and descending, appears to become adherent. The author observes that in the case of the steam-jet the minute particles of water, each consisting of minute molecules, must necessarily collide frequently with each other, and therefore it would seem that they ought to behave in the same manner as the larger drops of the water-jet, rebounding when unelectrified, and coalescing into larger drops when electrified. The fact that a much higher degree of electrification is required to produce the effect in the case of the steam-jet, rubbed sealing-wax being quite inoperative, scarcely seems to agree with this explanation; but the author suggests that the difference may possibly be due to the different sizes of the drops in the two cases, and in support of this he adduces the fact that if two electrified steam clouds are generated in close proximity to each other, they exhibit little, if any, mutual action; so that the electrification of the water particles must really be extremely small. Lord Rayleigh shows cause for believing that if the drops in the water-jet were all equally charged the phenomenon would not occur; and to whatever cause this inequality may be due, it would probably be equally effective in the case of the steam-jet. Lord Rayleigh has not suggested any explanation of the manner in which unequal charges of electricity of the same sign could bring about coalescence, and the author has not any suggestion of his own to make on the matter. Lord Rayleigh, in a Paper describing this phenomenon, points out its importance in connection with meteorological phenomena, and the author suggests that his own experiments with the steam-jet appear to suggest an explanation of the intense darkness characteristic of thunder-clouds, and also of the lurid yellow light by which their darkness is often tempered.

In concluding the account of his own experiments, the author stated that subsequent to their completion, and to his having offered the paper to the Physical Society, Professor S. P. Thompson had called his attention to a Paper by the late R. von Helmholtz (Wiedemann's *Annalen*, Vol. XXXII., p. 1), describing experiments made by him upon the electrification of a steam-jet. Helmholtz did not appear to have examined his jets by transmitted light, and made no mention of the great increase of opacity under electrification. In his experiments the jet was invariably observed against a dark background, illuminated by a ray of light coming obliquely from the front and shaded from the eyes. He found that when the jet was electrified, it was seen much more clearly and sharply defined against the background; and diffraction colours, similar to those seen in fog-strata, were exhibited. When the jet was very strongly electrified, a deep blue colour was produced, showing that very small mist drops were formed. When the electrification was slowly diminished, the blue tint became gradually paler, indicating the formation of larger drops, and this was succeeded by tints of purple, red, yellow, green, and ultimately, when the discharge became very feeble, pale blue again. Under certain circumstances all these different tints could be observed simultaneously in different portions of the jet.

The author stated that he had observed these diffraction colours in his own experiments, but he did not follow up the observations, as he found that they occurred when no electrical influence known to him was operating.

Helmholtz found that these condensation phenomena could be produced equally well by causes other than electricity, more particularly by the aid of flame. All the causes in question involved some continuous chemical action within the steam-jet, and he therefore thought the sudden condensation might be ascribed to molecular shocks upsetting the equilibrium of the supersaturated vapour, in very much the same way that a supersaturated saline solution can be made to crystallise by a slight disturbance. The author then illustrated the effect of combustion by holding a piece of burning touch-paper, made by soaking blotting-paper in a solution of nitrate of lead, underneath the jet, it being impossible to employ a flame, as it would discharge the electrification of the jet. It was immediately electrified in exactly the same manner as by electrification. The burning touch-paper appeared more convenient than the flame employed by Helmholtz, as it would be impossible to place the latter under the jet without dissipating it, and it would, therefore, be necessary to hold it on one side and blow the heated gases on to the jet.

The experiments described in Helmholtz's Paper naturally suggested to the author to try the effect of combustion on the water-jet, in which case, of course, the objection to the use of a flame did not apply. A Bunsen flame was therefore introduced into the jet, and it was found that when the air-holes of the Bunsen burner were stopped up, so as to make the flame luminous, the effect was generally similar to that of electricity, but was not obtained with the same perfect certainty; but when the burner was held a little below the point of resolution a great diminution of the scattering was invariably observed. The non-luminous flame had no effect whatever upon the jet. The author suggested that the effect of the luminous flame might possibly be due to its being electrified, as it is well known that luminous flames are electrified, in illustration of which he placed a luminous gas flame between the points of a Voss influence machine in action, the terminals being so far apart as to prevent sparks from passing, and it was observed that the upper part of the flame was repelled by the positive and attracted by the negative knob. The author mentioned, in concluding his Paper, that Helmholtz had suggested, as an alternative hypothesis to that of molecular shocks, that the electrical discharge of the flame or other exciting agent might possibly act by introducing small particles of solid matter into the steam-jet, which particles might act as nuclei upon which the water vapour might condense, as in Aitken's experiments upon the formation of fog.

DISCUSSION.

In the discussion which followed the reading of the Paper,

Prof. RÜCKER inquired whether the author had considered the effect of surface-tension upon the flame; for, as he pointed out, the higher the surface-tension the more rapidly would rupture take place. The surface-tension would be altered by the action of heat, and perhaps also by the introduction of solid particles, and both these would act in the same way.

Mr. RICHARDSON inquired whether the author had tried the effect of substituting red-hot iron instead of a flame, as in that case no solid particles could be introduced.

Prof. HERSCHEL remarked that the silky clouds often observed hanging over volcanoes after an eruption, might possibly consist of vapours of sulphurous acid and other substances condensed electrically in this manner.

Dr. FISON stated that in some experiments which he had made with a wire, held at various distances above a Bunsen flame, the greatest amount to which the potential of the wire was raised above that of the earth was about 2 volts, gradually diminishing as its distance above the flame was increased, until the electrification changed sign and increased negatively to a potential of 1·5 volts. It seemed to him that these charges would be too small to produce the observed effects.

Prof. S. P. THOMPSON observed that there seemed, according to the author's experiments, to be a curious contrast between steam jets and other clouds. For example, in Dr. Lodge's experiments it was found that fog could be dissipated by electrification. He inquired whether the author had observed the existence of any relation between the amount of change in the colour of the jet and the length of the spark.

Mr. BIDWELL, in replying, said since writing the Paper it had occurred to him that the effect of the flame might possibly be due more to the presence of dirt than to electrification, and, in illustration of this, he pointed out that Lord Rayleigh had found that the experiment did not succeed when the steam was obtained from soapy water. He had not tried the effect of using hot iron in place of flame, but he did not think it would produce any effect. Dr. Fison's observation of the greatest difference of potential obtainable from a flame was in agreement with what had been noticed by other observers, but he did not think the charge was necessarily too small to account for the effects observed when the flame was placed

Digitized by Google

between the terminals of an influence machine, for it must be remembered that though the flame might only be charged to the extent of a couple of volts or so, the difference of potential between the terminals of the machine would amount to some thousands of volts. He had not obtained any definite relation between the colour of the jet and the sparking distance; indeed, the colour appeared to be unchanged, whatever the length of the sparks, except on one occasion, when he thought he observed a slight tinge of slate colour when the sparks were very long, and the machine was turned very rapidly; but he was not able to obtain the result again upon repeating the experiment.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *November* 30, 1889.

The Overhead-Wire Agitation.—The overhead-wire question in this city has now come before the attention of the Grand Jury. When the Grand Jury first took the matter in hand, it was supposed that they intended to bring in some indictment against one or other of the Arc Light Companies to whose defective circuits the death of the lineman Feeks could be traced. But the Grand Jury do not appear to have found themselves in possession of such evidence as would warrant them in ordering an indictment, and it is now understood that they will restrict themselves to recommending various improvements in the matter of line construction, and in the character of the insulated wire used. It is possible also that this body may have some recommendations to make with regard to the subways, but it would be very hard to convince any intelligent and reasonable body of men that the subway system here is such as it ought to be. At the present time several of the leading thoroughfares have been ripped up again for the extension of the subway system, and the roads are consequently in a woeful state of mud and impassibility. It would be hard to say how often some of our leading streets have been turned up during the present year, but it is evident that the people have already reached the extreme of patience and endurance in this respect, and I should not be surprised to see legislation against any further tearing up of the pavements. As I close this letter, the Grand Jury have made a powerful presentation against the Board of Electrical Control, practically recommending its abolition.

Farewell Banquets to Mr. J. D. Reid.—Among the interesting events of the week have been the farewell banquets in this city to Mr. James D. Reid, of the Western Union Telegraph Company, who has been appointed United States Consul at Dunfermline, his native place. The first of these banquets was given to Mr. Reid by the Magnetic and Telegraph Clubs of this city, and on that occasion Mr. Reid was presented with a handsome gold medal suitably inscribed. In his response he gave some very interesting details as to his work in connection with the telegraph in its earliest years. He was the first man in the world to learn the Morse telegraph without an instrument; he opened the first telegraph office for commercial purposes in this country; he was the first man to introduce iron wire into the telegraph service of America; he was the first man to devise means for protecting the circuits from lightning, and was rewarded with a silver medal by the Franklin Institute; he was the first Superintendent of Telegraphs ever appointed, and he sent the first President's Message that ever passed over the telegraph wire. These were but a few of his interesting exploits in his early days, a fuller record of which, as well as of the whole development of the telegraph service, may be found in his own interesting "History of the Telegraph in America." Mr. Reid was also a close friend of Prof. Morse. The interest that attaches to Mr. Reid's career, however, is not merely that of a pioneer, for what has mainly distinguished him during his long telegraphic career has been his kindliness and gentleness, the most forcible expression of which may be found in the Telegraphers' Mutual Benefit Association, which he established, and which, in the course of a few years, has been the means of an immense amount of good in securing insurance benefits to the widows and orphans of telegraph officials and operators. The second dinner to Mr. Reid was given him by the Western Union officials and by a number of his personal friends.

A New System of Interior Wiring.—Attention has been called in the electrical papers this week to the system and methods of the Interior Electrical Conduit Company, which has been busily engaged in elaborating a system of interior wiring for incandescent work. Here, hitherto, the methods employed in interior wiring have been such as probably you are familiar with in England, *i.e.*, the wires have been carried along the walls and ceilings externally, and covered by mouldings, or have been buried in the plaster out of sight. Work on either of these methods can, of course, be well done; but it is only too often done badly. The mouldings are clumsy and badly put up, disfiguring the paper, or other coverings, and if the wires have been buried in the plaster, there have been numerous grounds, leading to chipping and breaking away of the walls and to great annoyance and expense. In the system elaborated by the Company named the wires are all carried through the building in conduits made of papier-mache, subjected to treatment with some bituminous asphalte compound, which renders them non-conducting and impervious to moisture. The tube is made in lengths of about ten feet, in sizes ranging from $\frac{1}{4}$in. to $1\frac{1}{4}$in. inside diameter, and these lengths are joined together by sleeve couplings, and can be right-angled or be fitted with elbows for rounding curves and corners. These tubes terminate in junction boxes and switch-closets, and hence the building can be tubed throughout before an inch of wire is put into it. Then the wire can be easily drawn in, in accordance with the wants of each floor, and the whole system can be quickly put into operation. One of the ideas in connection with the system is the use of twin conductors. Another detail of this system is that the wiring is done on what is called the distribution method—that is to say, instead of running the main conductors clear through the building from the dynamo to the top floor, and taking off a feeder on each floor, distribution points are located midway in the installation, and from those the sub-circuits are run; so that down to the last lamp a system of equalised pressure and perfect balance is maintained, with the further result that all the controlling devices are located in familiar places and are easily found. There seems little reason to doubt that the system as worked out is a marked advance in the art of interior wiring, and that it is likely to come into very general use. One of its great features of advantage, aside from questions relating to insurance, is that it makes provision for the future introduction of the light.

The Heating Effect of the Current in Conductors.—At the last convention of the Edison Association, held at Niagara Falls, Mr. A. E. Kennelly, well known to your readers, and now at the Edison Laboratory, read a most instructive Paper on the heating effects of the current in conductors. The great value of Mr. Kennelly's work consists in the fact that he has, by actual experiments over a wide range of currents and sizes of wire, to a certain extent verified some of the laws before arrived at; and, on the other hand, he has shown wherein they fail to express the truth, and the causes which lead to this discrepancy. He also takes up the subject of the accuracy of the rules promulgated by various electrical bodies—such, for instance, as the Safety Rule of the Board of Trade and the later one of the London Institution of Electrical Engineers, and shows where incongruities arise when these rules are carried out in practice. It would take me too far to go into the whole of Mr. Kennelly's work, but the publication of these tests, which have recently been begun in the *Electrical World*, is a valuable addition to the literature of this subject. The many diagrams accompanying the Paper show very graphically the behaviour of the wires under different conditions.

Electric Power for Church Organs.—A few weeks ago Dr. Talmage's great tabernacle was destroyed by lightning, and so great is the appreciation of the electric light among Dr. Talmage's people, that in rebuilding the sanctuary they propose to have what will be, practically, the largest electric plant to be found in a church anywhere. It is a remarkable fact, worthy of note here, that throughout the country large numbers of churches are now being supplied with electric power for the operation of their organs. There are several interesting electrical plants in miniature to-day in the churches of New York City. One, for example, at the Church of the Holy Trinity, consists of a gas-engine of $\frac{1}{8}$ horse-power, a small dynamo, a storage battery, the necessary automatic cut-outs, and an

Digitized by Google

automatic battery switch. Another plant, in St. George's Church, consists of a steam-engine of ¼ horse-power, and a little dynamo of 100 watts capacity. In the electric organ of this church, the insulated wire circuits are over 37½ miles in length, and there are 438 electro-magnets. This instrument has been played electrically for nearly three years, without showing any defect whatsoever. Another organ played electrically can be found in St. Paul's Church, one of the oldest in the country. In fact, the instances of this kind are so numerous and are supplemented by so many examples of church electric lighting that, as has been remarked, the time is not far distant when an electrician will be as well recognised an adjunct to the staff of every church as the clergyman and the sexton.

The Delany Telegraph Line Adjuster. — On the same evening, Mr. P. B. Delany brought before the Institute his telegraph line adjuster, by means of which all the way stations on the line have their relays kept in adjustment, so that, practically, any interruption of traffic in any weather is made impossible. With the recent improvements made in it, it was shown at the meeting in practical operation, and elicited many favourable comments from those present. Mr. Delany also described and showed a specimen of his improved gravity cell, in which both the zinc and the copper crystals are enclosed in paper, by which much of the injurious local action is avoided.

CORRESPONDENCE.

W. T. HENLEY'S TELEGRAPH WORKS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. W. Fowler, Chairman of the Fowler-Waring Cable Company (Limited), is reported to have stated at that Company's statutory meeting on the 6th inst., "We found a place on the Thames, at North Woolwich, formerly used by Mr. Henley, a 'great' maker of cables, but long since deceased."

As this statement may be taken to imply that the late Mr. Henley ceased to manufacture cables after giving up the works Mr. Fowler referred to, I beg to state that Mr. Henley forthwith adapted adjoining works and fitted them with the most modern and approved machinery for cable-making, and that these latter works, and all Mr. Henley's patents connected with submarine and other cables, were, in 1880, sold to our Company, Mr. Henley continuing the management until his decease in 1882.

A large proportion of your readers are, of course, aware of the continued activity of these works, as amongst your readers are, no doubt, included most of our customers; but to avoid any likelihood of error we shall be glad if you will kindly insert this letter in your next issue.

As a matter of fact, since Mr. Henley's decease the Company has reaped the benefit of the great development of electrical industries, and the business has tripled or quadrupled since 1882, many tons of copper being now used per week for electric light conductors alone, in addition to which we have considerable employment in making telephone, telegraph, and other wires and cables, our out-turn of submarine telegraph cable during the present year having exceeded a thousand nautical miles.—

Yours, &c., G. SUTTON, Manager and Secretary,
W. T. Henley's Telegraph Works Company (Limited).
27, Martin's-lane, Cannon-street, London, E.C.,
December 10, 1889.

THE SMITHFIELD CLUB SHOW.

This Show was commenced on Monday last at the Agricultural Hall, Islington, London, N., and has been very fairly attended. The Show contained the usual features, but is noticeable for an almost entire absence of any display of electric light or power. We cannot but deplore the lack of enterprise shown by our electric light and fittings companies in this respect, both here and at the Royal Agricultural Society's Show at Windsor (where it will be remembered a similar apathy existed), in not taking advantage of the exceptional opportunities offered of bringing the various applications of electricity to domestic and other purposes before a section of the public who have few chances of extending their knowledge of what is being done in the direction of lighting and transmission of power. Whilst the absence of exhibits directly electrical is to be regretted, there are, however, to be seen at the Show some very fine examples of engines, &c., suitable for the electric light. Brief reference is appended to the more important of these:—

MESSRS. DAVEY, PAXMAN, AND CO.—At the firm's exhibit are an 8 horse-power improved portable engine with single cylinder, an 8 horse-power horizontal fixed engine (Class A), a 6 horse-power improved high-pressure girder engine (Class B), and a 4 horse-power "Windsor" quick-speed vertical combined engine. The latter has been specially designed to meet the requirements of electric light installations. All the wearing surfaces are very large, to allow the engine to be worked for many hours without stopping; the crank-shaft runs in three very long gun-metal bearings, and special means of lubrication are provided to enable the engine to run for long periods without adjustment. Messrs. Davey, Paxman, and Co. have supplied one of these engines for driving the electric light at Windsor Castle; and they have been employed in driving electric light machinery in London, Manchester, and Paris. Paxman's automatic expansion gear is applied to the high-pressure cylinder of each engine, and is controlled directly by the governor. The fly-wheel is made specially heavy for electric light work, and is turned on the face to receive a driving belt. The firm also show a 4 horse-power "Essex" patent vertical boiler.

MESSRS. MARSHALL, SONS, AND CO. (LIMITED).—This firm have on view, amongst their other exhibits, a new pattern self-contained horizontal fixed engine, fitted with Moore's patent crank-shaft, governor, and balanced slide valves; a new pattern independent vertical engine, similarly fitted; and a 10 horse-power (nominal) compound stationary engine erected underneath a locomotive multitubular boiler, and fitted with Hartnell's automatic expansion gear, automatic sight-feed lubricator, &c., both engine and boiler being constructed of ample strength for a working pressure of 140lb. to the square inch.

MESSRS. RANSOMES, SIMS, AND JEFFERIES.—This firm exhibit a large collection of their well-known machines and implements, among which may be mentioned a 10 horse-power long-stroke stationary engine, in which the main frame is in one casting of the circular hollow type, the engine being specially suitable for mills, factories, &c. There is also a 7 horse-power short-stroke stationary engine on cast-iron foundation, the cylinder of which, with its valve chest, is bolted to the end of the engine frame, making a strong and compact engine.

MESSRS. ROBEY AND CO. (LINCOLN).—Among this firm's exhibits is one of their well-known compound "Robey" semi-fixed engines, fitted with their patent automatic governor and link expansion gear, by which the utmost economy of steam, with perfect regularity in speed, is secured. Recent carefully-conducted tests show that Messrs. Robey's improved compound engines work with a consumption of less than 2lb. of Welsh coal per horse-power per hour when developing two and a-half times their nominal power. There are also shown an E type horizontal fixed engine, fitted with patent triple expansion gear; a D type horizontal fixed engine, and a horizontal fixed engine with medium stroke, both fitted with automatic governor and link expansion gear, for which it is claimed that practically constant speed is maintained with great variation of load. These engines are made self-contained on one massive cast-iron foundation, with which are cast the main bearings; and they take a fly-wheel on either side—a clear gain where space is limited. A new design of vertical engine and boiler combined is also shown, with the main bearings, blocks, and piston guides cast in one piece with the engine framing, as well as a vertical high-speed engine designed to work with high steam pressure, which, when used for electric lighting, is mounted on a cast-iron base plate, the other end of which carries the dynamo.

MESSRS. CLAYTON AND SHUTTLEWORTH.—No engines specially designed for electric lighting purposes are shown by this firm, but they exhibit a number of their well-known make, one of which is an 8 horse-power portable engine, fitted with jacketed cylinder and continuous feed pump, to which is attached a very efficient water-heater, a reversing eccentric which admits of the fly-wheel running in either direction, and governor and duplicate safety valves (one in locked case): the steel crank shaft is sufficiently long to receive a pulley at either end. There is also shown a 10 horse-power fixed engine erected on a metal bed-plate planed at top and bottom; it is provided, in addition to the feed pump, with a patent exhaust injector for supplying the boiler, and connected with the steam pipe is a vacuum automatic sight-feed lubricator in lieu of the usual cylinder grease cock.

MESSRS. JOHN FOWLER AND CO. (LEEDS).—This firm show their well-known type of compound semi-portable engine of 8 horse-power, specially constructed for electric lighting, and fitted with Hartnell's patent automatic expansion gear on both cylinders. It is claimed that the engine is not only economical in working, but is extremely well governed, and is incapable of exceeding by more than 1 or 2 per cent. its mean speed when the load is suddenly

Digitized by Google

removed, and will not fall below the mean speed by a greater amount when the whole load is suddenly thrown on. Messrs. Fowler and Co. also exhibit several other engines of their well-known type.

Messrs. Richard Hornsby and Sons (Limited).—This firm's exhibit includes an 8 horse-power portable engine of substantial design, with wrought-iron crank-shaft, brackets, and all the working gear and shaft made of steel, with very large wearing surfaces, and a 4 horse-power vertical winding and pumping engine, specially designed for use where breakdowns would be disastrous, and intended for work in mines. A fine example of Messrs. Hornsby's compound underneath engine is on view, of which a large number are in use for electric light purposes, and for driving machinery in workshops, &c.; the engine is said to be very economical, is fitted with sight-feed lubricator, and when used for electric lighting other special arrangements are added. A model is also shown of a fixed stationary engine made by this firm, from 8 to 100 horse-power, of a design well adapted for electric lighting purposes: it is very strong, and is fitted with Hornsby's automatic gear for economical working.

Messrs. Brown and May (Devizes).—This firm have on view two examples of the "Knight" patent paraffin oil engine, which is described as a "gas engine that requires no gas supply." It is claimed for this engine that it is suitable, amongst other things, for electric-light work.

Mr. E. S. Hindley, of Bourton, Dorset, has his usual well-arranged exhibit of small engines, most of which are of his well-known types.

Messrs. Pfeil and Co. have an excellent display of lathes, including a large variety of the "Electrician" lathes. Their exhibit, which also includes punching, shearing, and drilling machines, is one of the most noticeable in the Show.

Among the miscellaneous exhibitors who have good displays of engines, engineers' stores, &c., may be mentioned Messrs. Allchin, Linnell, and Co., of Weston-street, Northampton, who have some examples of their well-made traction engines on view; and Messrs. W. H. Willcocks and Co., of Southwark-street, London, S.E., who have a large display of machine belting, &c.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Okonite Wire.—Okonite-covered wire has met with considerable favour in America for telegraph and telephone purposes, as well as for electric light leads. This insulation is somewhat more expensive than the usual rubber compounds, but experience has shown that it far surpasses them in durability, toughness, and resistance to the deteriorating influence of the weather. Variations of temperature, also, have but little effect on its insulating properties. In Chicago, where there are some 80 miles of okonite insulated wire in use in the electrical conduits, it has been exposed to an exceptionally severe test without breaking down. The wires in Chicago are run underground in the sewers on brackets coming out from the wall with the ordinary common glass insulators, and when the Chicago river is in flood the wires are completely under water. As the E.M.F. averages about 2,000 volts the test is sufficiently severe. The sole agents in this country of the Okonite Company, of New York, are Messrs. Laing, Wharton, and Down, of New Bond-street.

Chemicals for Batteries.—Several samples of sal ammoniac and chloride of ammonium, for batteries, manufactured by the Netham Chemical Company (Limited), of Bristol, can be seen at this office.

The Consolidated Telephone Construction and Maintenance Company (Limited).—This Company have recently issued an illustrated circular giving descriptions and prices of their telephones for domestic use. It should be noted that these telephones are for export only. Among the illustrations is a diagram showing this system of domestic telephony.

The General Electric Company (Limited).—We are in receipt of four electrical engineering cards issued by this Company, giving price-lists and illustrated descriptions of Edison fittings, flexible cords for table and pendant lamps, porcelain ceiling rosettes, pendant accessories, brass galleries and caps, jointing materials and sundries.

Messrs. John Davis and Son.—We have recently received two catalogues (A and B) from this firm. The A catalogue deals with mining, mathematical, surveying, and engineering instruments, and miners' safety lamps; the B catalogue deals with electric light plants, transmission of power, electric blasting apparatus, electric signalling apparatus, special outdoor fittings for electric lamps, lightning conductors, &c.

Messrs. J. G. Statter and Co.—This firm's recent list includes tabulated particulars relating to the "Statter" dynamos and motors, with illustrations of both, as well as of a combined engine and dynamo for ship lighting, or for use where space is limited.

Messrs. Poole and White.—This is the title of a new firm of electrical and mechanical engineers with offices at 58 and 59, Bread-street, Cheapside, London, E.C.

Personal.—Mr. W. C. Muir, has, we are informed, withdrawn from the firm of Messrs. Muir, Mavor, and Coulson, of Glasgow.

Tenders Wanted.—The Shropshire Iron Company (Limited) are asking for tenders for lighting. Particulars will be found in our advertisement columns.

Sales by Auction.—We would remind our readers that Tuesday next, the 17th inst., is the date fixed for the sale by Messrs. Wheatley Kirk, Price, and Goulty of the stock and stores of Luther Hanson and Co. (Limited), in liquidation. The sale takes place at North Bridge Electrical Works, New Bank, Halifax, and commences at 10 for 11 o'clock prompt. The catalogues are now ready, and can be obtained of the auctioneers, or of Mr. James Duff, the official liquidator, Barum House, Harrison-road, Halifax. The sale includes the patent rights, patterns, and drawings for the Luther dynamo and arc lamp, as well as a number of new dynamos, one of which was successfully run at the 1887 Manchester Exhibition.

——— Mr. Joseph Dawe will sell by auction, at the Mart, Tokenhouse-yard, London, E.C., on Wednesday next, the 18th inst., at 2 o'clock, the British and foreign patent rights of Douse's Fire-checking Apparatus. Further particulars will be found on page iii. of advertisements.

COMPANIES' MEETINGS & REPORTS.

The Fowler-Waring Cables Company (Limited).

The first general meeting of this Company was held on the 6th inst., at Winchester House, Old Broad-street, under the presidency of Mr. William Fowler.

The SECRETARY (Mr. Geo. Neill) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, you are aware that this is not a meeting for business. It is merely a formal meeting, under the Act of Parliament, which we have to hold within four months of the formation of the Company. You will understand that, immediately the Company was formed, the first point we had to consider was, where shall we proceed to work and arrange for procuring the machinery and everything necessary for the work of the Company? We decided, if possible, to have our work commenced in London, and after a great deal of inquiry we found a place on the Thames at North Woolwich, formerly used by Mr. Henley, a great maker of cables some years ago, but who is long since deceased. It is a curious fact that in Mr. Henley's time I went down to see that place and his works, and when it was suggested to me that this place, so long idle, would be suitable for us, I said I thought so too, for, unless I was mistaken, Mr. Henley was a man who did everything very well. We, therefore, after a great deal of consideration, made a contract with the owners of this property, giving us the property for a certain time at a very moderate rental, with an option at any time within four years to buy the freehold at a rate which is just about 20 years' purchase of the land. Of course, when I say the land, I mean the land and all the buildings upon it which Mr. Henley had put up. Last week I renewed my acquaintance with the place after we had done a great deal upon it, and I assure you I was astonished at finding how accurate my memory had been, for the character of the building was such that I am certain we have made a most excellent bargain. I say so without hesitation, because its acquisition was owing more to others than to myself, though I gave it my hearty sanction when I understood the terms that were suggested. It will, of course, cost us something to place the buildings in condition to carry on our business, but the expenditure will not be very material. They have been made so substantially, and they are so grand in their way—if I may use such an expression relative to buildings for manufacturing purposes—that I really believe it would cost you all the money that we shall have to pay for the property, if we buy it, to put up these buildings to-day. I therefore think that we have not lost any time, and that we have done a work for you which will be very satisfactory to you in the result. The machinery is actually, to some extent, on the place. The engine and boilers are up this very day, the shafts are turning round, and I believe that very early in the next year, 1890, we shall be in a position to take orders for cables. Of course, as you are aware, from the prospectus, we have not been without business in the meantime, because under the arrangements with the firm of John Fowler and Co., of Leeds, they hand over to us the profit on their business, less a fair percentage for their work, and they have been busily making cable ever since the time the Company was formed. We are therefore really earning some money now, and I have very little doubt—I think I may say I am confident—that this Company will be a real success. I am extremely cautious about making promises or prophecies, as I think both are very dangerous things, but I believe we have got hold of a business which will prove very satisfactory to you as shareholders. I really do not know that there is anything else I can say. I repeat that we have not lost an hour in endeavouring to set to work, and we are likely to be at work practically within four months of the formation of the Company. I think we could not very well have done more than that. It is only through the accident of finding this place all ready for use that we are enabled to make that statement. If we had had to buy land, and put up buildings, I really do not think we should have done it under a year; but as it is, we are very likely, as I said, to be at work four months from the time of the formation of the Company. I have no resolution to propose, but merely to make this general statement as to the condition of the concern; but I shall be delighted to answer any question that any shareholder may have to put to me.

Mr. POTTER stated that through him a considerable number of the shares of the Company had been taken in Leeds, and recently something had occurred there which had rather exercised the minds of several of the shareholders, and his own, too. They understood that the Fowler-Waring mode of making the cable with the covering of lead was the only one there was, and that the patent rights were secured to this Company. At the

present moment, however, in Leeds, cables were being laid which appeared to be nearly the same thing; and to relieve the minds of several of the shareholders who had been to him, he would like to ask if that were the same thing, seeing that they had been under the impression that this Company had the monopoly of the patent. Mr. Eddison would know what he was referring to. The cable in question had been laid near the Queen's Hotel. The core of the thing appeared to be the same; but it seemed to be lead-covered cable like the Fowler-Waring. He spoke himself without knowledge of the thing, and only because several persons had been to him and asked him if he could find out anything about the matter.

The CHAIRMAN: I will ask Mr. Eddison to answer the question.

Mr. EDDISON: The cable you refer to as being laid at the present time in Leeds is one that has been supplied from Chicago by the Western Electric Company to the National Telephone Company—a 100-wire telephone cable. The wires are covered with lead, but they are drawn into lead pipes, whereas we put the covering on the lead; and the covering in the case of the American wires is in very short lengths. I may also add that the National Telephone Company have given us an order for Leeds. One cable will be laid next week, and it is double the length of the Chicago cable.

Mr. POTTER said he had thought it only his duty to ask the question.

The CHAIRMAN: I am glad you did so, but I think it is clear from what has been just said that the American cable is totally different from ours. If we found anyone infringing our patent we should soon bring him to book.

Mr. EDDISON: If you examined the American cable you would find a plumber's joint every 40 feet.

The CHAIRMAN: We, of course, must not begin an action until we are quite certain that our rights are being infringed.

We will now consider the statutory meeting closed, and I have to move a formal resolution as to a change in the Articles of Association which is demanded by the Stock Exchange before we can get a settlement. He then proposed a resolution, making certain alterations in Clauses 31 and 77 of the Articles of Association.

Mr. FLEMING seconded the resolution, which was unanimously agreed to.

The CHAIRMAN stated that that closed the business of the meeting. It would be necessary to hold a meeting to confirm the resolution just passed, and they proposed to hold it on the 20th inst. at the offices of the Company, when he hoped that a few gentlemen would be kind enough to attend to form a quorum. It was only a formal matter, but it had to be gone through so as to get the settlement on the Stock Exchange.

Mr. GATHORNE-HARDY then proposed, and Mr. POTTER seconded (at the same time expressing his satisfaction at the business-like conduct of the meeting), a vote of thanks to the Chairman.

The CHAIRMAN, in reply, assured the shareholders that, for many reasons, he would do all in his power to make the Company a success.

The Gülcher (New) Electric Light and Power Company (Limited).

The following is the report of the Directors of this Company for the year ended June 30th last. The Directors state that they are now able to present to the shareholders the first balance-sheet, for the twelve months ended June 30, 1889, of the reconstructed Gülcher Company. The shareholders are already so well acquainted with the conditions of the reconstruction of the Company that the balance-sheet calls for but few observations. Although the agreement for sale by the liquidator of the old Company was signed on February 23, 1888, the new Company was unable to complete its purchase until August 31, 1888, and, therefore, had been on June 30, 1889, in existence as an actually trading company for ten months only. The Second Debentures were issued to enable the Company to carry out the lighting of the City of Wellington, New Zealand. The value at which the New Zealand contract is assessed in the balance-sheet is the actual cost price expended in time and materials on June 30, 1889. The central stations at Wellington were finished in the month of September last, and the public lighting has proved to be thoroughly satisfactory. The commercial success of this undertaking will depend entirely upon the ability of the Company to provide capital for private lighting. The Directors have laid down plant capable of distributing the current to the remotest parts of the city, and with a comparatively small further outlay a remunerative revenue could be obtained. The Directors propose to carry forward the surplus appearing to credit on the balance-sheet. Particulars of other contracts undertaken and carried out during last year will be supplied at the general meeting, when a detailed profit and loss account will also be submitted to the shareholders. Several alterations have taken place in the Board of Directors since February 23, 1888, but all the Directors on the Board at present are original Directors of the Company. This being the first general meeting of the Company, all the Directors retire, but, being eligible, offer themselves for re-election. The Directors having appointed Mr. Russell Day, formerly secretary of the Gülcher Company, to investigate, on their behalf, the accounts involved in the transfer of the Gülcher Company's business to them, decided to appoint him to audit the first balance-sheet and profit and loss accounts. It will be for the shareholders to appoint an auditor or auditors for the ensuing year.

NEW COMPANIES REGISTERED.

FOREIGN AND COLONIAL ELECTRICAL POWER STORAGE COMPANY.—Objects, to carry on in any part of the world the business of manufacturing and working storage batteries and machinery, and the use of electric, magnetic, or other force, adopting therefor an agreement (unregistered) of November 22, 1889, made with the Electric Construction Corporation, Limited. Capital, £100,500, in £5 shares, of which 100 are founders' shares. Subscribers of one ordinary share each are: Sir Daniel Cooper, Bart., G.C.M.G., J. Irving Courtenay, James Balfour, James Pender, J.P., Frederick Green, Reginald Mackenzie, T. H. Horwood. Directors (three to seven), Sir Daniel Cooper, John Irving Courtenay, James Pender, James Balfour, and Frederick Green, as above named, the first mentioned three not acting until after adoption of agreement. Qualification, £500, in shares or stock. Remuneration, £1,000 per annum, and 10 per cent. of profit after 10 per cent. dividend; total, however, not to exceed £5,000 in any year, and such sums are to be divisible. Directors may borrow on mortgage debentures to the extent of £100,000 without sanction of general meeting. Registered, December 3rd, by Renshaws, solicitors, 2, Suffolk-lane.

MORRIS BROTHERS (LIMITED).—The Company was registered on the 5th inst., with a capital of £5,000, in £1 shares, to acquire the business of Messrs. Morris Brothers, of Hartington Works, Branston-street, Birmingham, electricians and general scientific apparatus manufacturers. Registered without special articles. Solicitors, Messrs. Kerly, Son, and Verden, 14, Great Winchester-street, E.C.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 6th amounted to £4,944.

ROCHESTER, CHATHAM, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The second annual report of the Directors of this Company announces that although unable to show a profit out of which to declare a dividend, it is now felt assured that the business is established on a commercially sound and fairly remunerative footing. Quite two-thirds of the lights have been applied for and are now installed, and, as orders are still coming in, it is hoped by the end of the year that the remainder will be disposed of. A change has taken place in the management of the works by the resignation of Mr. Parker and the appointment of Mr. A. Maund.

STOCK EXCHANGE.—The Committee have appointed Tuesday, the 17th inst., the special settling day in the Electric Construction Company (Limited)—shares, Nos. 101 to 45,100; and the National Telephone Company (Limited)—49,825 additional shares, Nos. 386,876 to 436,700 (to be quoted in the official list).

WESTMINSTER ELECTRIC SUPPLY CORPORATION (LIMITED).—The issue was announced on Friday last of 60,000 shares of £5 each, of which 20,000 have already been taken.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 6th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,538.

THE NON-CONDUCTOR OF ELECTRICITY.

WAREHOUSE.

VULCANISED FIBRE,

PATENTED.

This new material is supplied in two qualities, Flexible and Hard.

The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.

It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.

The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.

Sold in sheets, 5ft. 6in. by 3ft. 6in., varying in thickness from 1-50in. to 1in.

FACTORY.

FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

JABLOCHKOFF'S
DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITED)

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Nalder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

MANVILLE & MADGEN, *Managing Directors.*

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 605.—Vol. XXIV. FRIDAY, DECEMBER 20, 1889. Price Fourpence.

NOTES.

It will be remembered by our readers that at the beginning of the present year (*Electrician*, March 22nd) Mr. Edison's Canadian incandescent lamp patent was cancelled by the Commissioner of Patents, on the ground that it was void from failure to manufacture in the Dominion within two years, as required by law. Owing to a doubt as to the jurisdiction of the Commissioner, the action was reheard, and a decision maintaining the validity of the Canadian patent has now been given by the Minister of Agriculture. As it is uncertain what is the exact legal effect of the expiry of a foreign patent upon one held in the United States, this result will tend to still further strengthen the Edison patent in America.

For a Company which has not yet been two years in existence, and which has only been able to get fairly to work within the last five months, the record of the Metropolitan Electric Supply Company, as set forth in the report of the Directors, is very creditable. The capacity of the three existing central stations is taxed to the utmost, and although the stations at Manchester-square and Waterloo Wharf are expected shortly to come into operation, the Directors deem it advisable, in view of the increasing demand for current, to double the plant at Sardinia-street, and to commence the construction of a station within the Strand district. Additional stations are, moreover, contemplated for the City and Paddington. Such substantial progress as this is most encouraging. A coloured map, which is issued with the report, shows the areas allotted last Session to the various electric supply companies; and it brings out very clearly that, as far as mere size is concerned, the lion's share of the lighting of the metropolis has certainly fallen to the Metropolitan Company and the London Electric Supply Corporation.

The proposal for a partial amalgamation of the five leading engineering societies, which was brought forward by Major Flood-Page at the annual general meeting of the Institution last Friday, does not, it seems to us, contain the elements of success. United action for temporary purposes may often be very advantageous, but the tendency of the times points, we think, far more towards sub-division than amalgamation. A second proposal of Major Flood-Page was that the Institution of Electrical Engineers should undertake examinations and issue certificates of competency as electrical engineers. Whether the goal aimed at be an improvement in the present standard of admission to the Institution, or merely the weeding out of incompetent workmen, we think the Council would be ill-advised if it were to adopt this suggestion. The former object would, we are confident, be better attained by a more rigorous scrutiny of the claims of the candidates for admission, while the task of weeding out incompetent workmen falls more within the province of our technical schools than of the Institution of Electrical Engineers.

We commence this week a series of articles on "Magnetism in Iron and other Metals," from the pen of Prof. Ewing, whose researches in this direction are too well known to need comment. At a time when the phenomena connected with the magnetisation of iron have assumed such prominence in practical work, we venture to think that this series will prove especially interesting and instructive.

The sensational stories of deaths from electricity which are being telegraphed almost daily by the New York newspaper agencies to this country would be simply absurd if they were not so inconveniently inopportune. Even if they were true, which in most cases they are not, and even if the "pathological" comments on the victims were as edifying as they are ridiculous, there is no apparent reason why a death from electricity, any more than a death from inebriety, should be proclaimed all over the two continents. The chief reason we take to be that the people of New York, not before time, have become disgusted with the hideous disfiguration of their thoroughfares by the indiscriminate erection of poles and wires to a quite intolerable extent, and are glad to seize on any pretext for getting rid of the nuisance. But we are not afflicted in any such degree on this side the Atlantic, and our American brethren might have a little mercy on us who are only just feeling our way with electric lighting, and whose intending customers are likely to be scared by the accounts that reach them from a quarter where it has long been well established. If New York electrical engineers are so negligent, or so incompetent, as to leave their wires in a dangerous condition, the least they can do is to keep their servants out of harm's way.

As an example of how little electricity has to do with many of these sad accidents in which the American daily press takes such morbid delight, we cannot do better than quote the following from our esteemed contemporary the *Electrical World*

Digitized by Google

of New York:—"A few days ago a sensational paragraph went the rounds to the effect that a boy at Chattanooga, while under one of the cars, cleaning it, made contact accidentally with the current wires and was killed. As only 500 volts is used on electric roads, the story seemed apocryphal, but it 'went.' The true account of the accident now shows that no current was on at all at the time. The coloured boy in question was under the cars, wiping off the motors with waste. A groan was heard, and then some men at work in the shed found that the boy had fallen asleep, tipped his lamp over and set fire to the waste and to his clothing. He died from the burns six weeks later. Nearly all the 'electrical accidents' we have investigated have turned out to be of this nature, and we are becoming rather tired of exposing them."

It is announced by our American contemporaries that a fusion has been effected between the Edison General Electric Company and the Sprague Electric Motor Company, between which bodies a friendly alliance had long subsisted. Mr. Edward H. Johnson, whose business ability in pushing the Edison interests is so well recognised on this side the water, has also for some years been President of the Sprague Company, and it is to his exertions that the amalgamation of interests is due. In a recent interview on the subject, Mr. Johnson stated two points, to each of which, though for very different reasons, we draw the attention of our readers. He stated that many of the Edison generating electric stations were now not primarily electric lighting stations, though originally established as such, for so great had been the development in the use of electric motors in the various industries that the main work of the stations was now to supply electric motive-power. He maintained that the motive-power business was rapidly rivalling the lighting business, and would unquestionably surpass it in the near future in the amount of capital employed and in output. We commend this first point to our English readers. It does not surprise us: but it is a good sign.

Mr. Johnson's second point is, however, surprising. "He claims that, based as they both unquestionably are upon fundamental patents—Edison for generating and distributing and converting into light, and Sprague for distributing and converting into power—it requires no great stretch of the imagination to foresee a future for the combination equalled by no new industry, not excepting the telephone, which this most fruitful of inventive nations has yet produced." If the words, which we quote verbatim, have any meaning, they imply that Edison is the inventor not only of the glow-lamp, but also of the arc lamp, the dynamo, and of the means of distributing currents; whilst Sprague is the inventor of the electric motor, and that no one else will be allowed to distribute light or power in the States. Now, whatever is the extent of Edison's claim to the invention of the glow-lamp, he certainly did not invent the arc lamp, nor the insulated wire conductor. And as for the dynamo, were not the dynamos of Gramme, Siemens, Brush, and Thomson-Houston at work at the date when Edison was racking his brains over his tuning-fork dynamo and his Faradaic machine? And with regard to Sprague, is it not well known that Gramme's and Siemens's machines were in use as motors before that distinguished officer had even begun his electrical studies in the Naval Academy? whilst it is notorious that the so-called Sprague method of winding motors with a series coil to weaken the field-magnet, which he invented in 1884, was described by Ayrton and Perry in 1882. Mr. Johnson's broad claim to control the motor industry by Sprague's patents is a little too broad. We commend this, his second point, to our American readers.

Our enterprising evening contemporaries, who eagerly snap up what they suppose to be news about electrical discoveries, have been busy circulating a report to the following effect:—It is well known that in every primary battery part of the current never gets out of the battery, but is wasted, and that there is consequently a waste of the zinc: a remedy for this has just been found by the great Mr. Edison, who, after thousands of experiments, has succeeded in discovering a simple fluid which has the remarkable property of preventing the useless consumption of the zinc. It now turns out that this "simple" fluid is a solution of caustic potash, and that the depolarising agent is compressed oxide of copper. Did no one ever hear before of the Lalande-Chaperon cell, in which these very substances are used? We were promised electricity for nothing and a profit out of the value of the waste products. What more could one want? Only this time when the great invention turns up again, it has got the great patentee's name upon it. *O sancta simplicitas!*

Our readers will find to-day another instalment of Mr. Kennelly's valuable Paper upon "The Heating of Conductors by Electric Currents," and right good reading it is, being the record of careful, intelligent, and thoroughly scientific work. Mr. Kennelly confirms Forbes's point that whilst the loss of heat by radiation proper is very nearly proportional to the elevation of temperature of the surface, the loss by convection currents in the surrounding air is by no means so. We heartily applaud Mr. Kennelly's researches, and wish he may long live to carry out such useful work.

Mr. Kennelly does not mention—though for all that he probably is not ignorant of—some researches on the heating of wires made by Mr. J. T. Bottomley, of Glasgow, some years ago, and which were communicated at the time to the Royal Society. Amongst other curious results brought out by Mr. Bottomley was the effect of an insulating coating upon thin wires: he showed that it was possible, using a conducting copper wire coated with an electric insulator, so to arrange the relation between the dimensions of the wire and its coating, the conductivity of the material and the emissivity of the surface, that the presence of the insulator shall keep the wire *cooler* than it would be without the coating. This curious experimental result had been predicted from theory by Sir William Thomson. Writing of this to the Editor of this Journal some time back, Mr. Bottomley recalled the king, in

Digitized by Google

"Faust," who had "a lusty flea," remarking that if the jacket ordered by the king for a creature of such minute dimensions had been of flannel, it would have kept him *cool*, not warm!

On Friday last Mr. Joseph Frederick Leeson, who was recently struck off the register of general practitioners by the General Medical Council, for acting as cover to Mr. Harness, brought a motion to restrain the Council from erasing his name from the register until the trial of the action which he is bringing against them. In support of the motion it was urged that the Council had not complied with their own rules, that certain matters had been before the Council which were not evidence, and that two of the judges were members of the Medical Defence Union. Mr. Justice North briefly put aside the first two reasons, and decided that, although the members of the Medical Defence Union were interested in the case, their interest was not of a pecuniary nature. The motion was, therefore, refused.

Volume I. of "Practical Notes for Electrical Students," by A. E. Kennelly and H. D. Wilkinson, is now ready. The first volume deals with batteries, potential, resistance, current and current indicators, tests and calibration work, and magnetic fields. This work is mainly a reprint of the series of articles entitled "Letters for Learners and Un-Professional Readers," which have recently been appearing in the columns of this journal. Our readers are, therefore, in a position to judge of the style and scope of the work. The price of Vol. I. is 6s. 6d., and it is published at *The Electrician* office.

Dover.—The Town Council has decided to proceed with their application for a Provisional Order.

Cambridge.—The Town Council has resolved to proceed with their application for a Provisional Order.

Portsmouth.—The Town Council has resolved to proceed with their application for a Provisional Order.

Royal Institution.—The first of Prof. Rücker's series of six lectures on "Electricity" will be delivered at the Royal Institution on Saturday, the 28th inst., at 3 p.m.

Rochester.—The Town Council have instructed Mr. Moulton, Q.C., to give the Corporation his opinion on a proposed Provisional Order of the Chatham Electric Light Company.

The Royal Society.—Among the Papers down for reading yesterday at the Royal Society was one by Mr. C. Chree, "On the Effects of Pressure on the Magnetisation of Cobalt."

Dunedin (New Zealand).—The Gülcher Electric Light Company, having completed the work of illuminating Wellington by the electric light, have now submitted proposals to the Dunedin City Council.

Ipswich.—The lighting of the Suffolk Cattle Club Show at Ipswich, which gave general satisfaction, was carried out by Mr. W. Sisling, the Ipswich representative of Messrs. Laurence, Paris, and Scott.

The Overhead Wire Agitation in New York.—Telegrams from New York state that the cutting down of the overhead electric lighting wires has recommenced, the injunction restraining the authorities having been removed.

Postal Telegraph Revenue.—The total receipts from the telegraph service paid into the Exchequer from April 1st to December 14th of the present year, amounted to £1,630,000, against £1,470,000 for the corresponding period.

Bristol.—The Electric Lighting Committee of the Town Council have requested Mr. Preece to furnish them during the present month with an estimate and specification for lighting the portion of the city described in his report as Section A.

The Liverpool Physical Society.—The meeting at which this Society was constituted was well attended. Nearly ninety names were at once handed in to the secretary for membership. Prof. Oliver Lodge, F.R.S., was appointed president, and on Monday next delivered his inaugural address.

Chester.—In moving the adoption of the recommendation of the Watch Committee, that the electric lighting Provisional Order be proceeded with, Alderman Johnson said they were in no hurry about it, but before the period over which the Order would extend expired perhaps something more would be known about electric power.

Bradford.—At the last meeting of the Gas and Electricity Committee of the Bradford Town Council, Alderman F. Priestman said the committee had no intention whatever of extending the electricity works at present. The committee would have a full load on their present installation before Christmas, the demand for current increasing every day.

Presentation to Prof. Tait.—In consideration of his long and eminent services as secretary of the Royal Society of Edinburgh, it has been resolved by the Council of that body to present Prof. Tait with his portrait. The commission has been given to Mr. George Reid, R.S.A., and the portrait is intended ultimately for the rooms of the Royal Society.

Electric Lighting Notices.—In the list of electric notices published in our issue of December 6th, the two companies who have applied for powers for Edinburgh should have been (i) the Scottish Electric Supply Company, and (ii) the Scottish House-to-House Electricity Company, the Brush Company not having taken the necessary steps required by the Board of Trade.

Electric Traction in Italy.—A Company, called the "Società Anonima della Tramira Elettrica Lodi-Borghetto San Colombarro-Chignolo," has been formed in Italy, with a capital of £20,000, to lay down and work a system of electric tramways between Lodi and various points in the neighbourhood. The necessary apparatus will be furnished by the Brush Company.

Technical Attaches.—The Vienna correspondent of *The Times* states that the Russian Government proposes shortly to appoint technical attachés to its Embassies and principal Legations abroad. Their duty will be to report to the Minister of Public Works on the improvements introduced into the working of railways and telegraphs and on practical scientific discoveries generally.

Newcastle. — According to the *Newcastle Daily Chronicle* arrangements have been arrived at between the Newcastle District Electric Lighting Company and the Newcastle-upon-Tyne Electric Supply Company to supply the electric light in Newcastle in such a way as not to interfere with the interests of each other, each company working by itself within an area mutually agreed upon. Both companies are now actively engaged in laying down their mains.

The St. James's and Pall Mall Company.—In a note in our last issue it was stated that at a meeting of the St. James's Vestry the previous week, a letter was read from the St. James's and Pall Mall Electric Lighting Company, stating that it was their intention to apply for a Provisional Order to construct two electric railways. We have since been informed that the report of the meeting upon which our note was based was incorrect, and that the St. James's and Pall Mall Company have no such intention.

The Electric Light for Manila.—Her Majesty's Consul at Manila, Philippine Islands, reports that the municipality is desirous of obtaining tenders for the lighting of the city and suburbs by electricity, instead of the present system of petroleum lamps. The total distance to be so lighted is about 36 miles, and the time for receiving proposals is limited to a period of six months, dating from the 1st ult. Further details and plans may be seen on application to the Commercial Department of the Foreign Office.

St. Helens.—The Board of Trade having informed the Corporation that it would not consider the withdrawal of its application for electric lighting powers a reason for refusing to grant a future application, the Gas Committee have now recommended the Council to withdraw the application during the present

Digitized by Google

Session. A sub-committee has been appointed to report upon the question of the supply of electricity, and it is expected that some practical scheme will be presented to the Corporation in the course of the next year.

The Institute of Patent Agents.—The first qualifying examination for certificates entitling to admission to the Register of Patent Agents, established under the Act of 1888, was held, November 18th to 23rd, by the Institute of Patent Agents, under the regulations passed by the Institute and approved by the Board of Trade, in accordance with the Register of Patent Agents Rules, 1889. The successful candidates were :—Mr. Thomas Henry Barron, of Huddersfield, and Mr. George Beloe Ellis, of London.

Electric Brake Trials.—Trials have recently been made at Birmingham on the London and North-Western Railway of the electric brake designed by Prof. Forbes and Mr. Illius A. Timmis. An entire train of carriages fitted with it are being constructed by Messrs. Brown, Marshall, and Co., of Adderley Park, for use on a line in Russia. The chief gain of an electric brake is rapidity of action. A train of average length will feel the brake power throughout its length almost instantaneously as against three or four seconds required by the brakes at present in use.

The Royal Society.—Amongst those who were elected to foreign membership of the Royal Society last week was Prof. Rowland, of Baltimore, for his determination in absolute measure of the magnetic susceptibilities of iron, nickel, and cobalt; for his accurate measurements of fundamental physical constants; for the experimental proof of the electro-magnetic effect of electric convection; for the theory and construction of curved diffraction-gratings of very great dispersive power; and for the effectual aid which he has given to the progress of physics in America and other countries.

Birkenhead.—At a special meeting of the Birkenhead Town Council, held on Friday last, the Town Clerk read the provisions of the "Birkenhead Corporation Electric Lighting Provisional Order." Mr. Bloor said it was a dog-in-the-manger policy for the Corporation to apply for a Provisional Order with no binding conditions attached to it, but which was merely intended to keep out companies who were willing to do the work. Alderman Rawcliffe: "It is to keep the power in our own hands that we take these steps, and prevent the streets of the borough being cut up by outsiders." It was finally decided to proceed with the Order.

Aberdeen.—The Gas Committee of the Town Council had under discussion on Friday last the report of the deputation who recently visited several towns in England to inspect the systems of electric lighting in operation. It was resolved to recommend that application should be made for both a Provisional Order and a Bill, the borrowing powers to be £50,000, and the Gas Corporation funds to be the security. It was also decided to divide the area to be applied for under the Order into two districts, to be lighted within two and four years respectively. The cost of providing an installation for the restricted area is estimated at £20,000.

A Smart Performance.—In consequence of the total failure of the Manchester gas supply, the Lancashire and Yorkshire Railway Company decided to light the Victoria Station with the electric light. Within six hours of the time the order was given, the most important platforms were lighted, and the whole station was brilliantly lighted with about 250 incandescent and a few arc lamps within 36 hours. The current had to be conveyed for about a quarter of a mile, and all the necessary circuits had to be run. The whole of the installation was carried out by the Company's telegraph and electric light staff, there being only about ten men on the work. The new light has since been running day and night, and steps are being taken to have the light fixed permanently

Dublin.—At the last meeting of the Town Council the chairman of the Finance Committee moved the adoption of the estimates of amounts to be paid by that committee out of the improvement fund for the year to end December 31, 1890. One of the items was a sum of £1,687. 10s., being the first of the yearly instalments of principal and interest in respect of the account loan of £50,000 for the purpose of supplying electricity for public purposes. After considerable discussion the estimate, reduced by a sum of £324. 1s. 2d., was passed. Alderman Dillon said the delay in the commencement of the works was principally due to the fact that though the licence for public lighting by electricity had been issued long since, the licence for private lighting had not been obtained till a few months ago. They hoped to have a portion of the city lighted by electricity next year.

Proposed Singapore-Borneo Cable.—At the meeting of the British North Borneo Company, on Wednesday, Rear-Admiral R. C. Mayne, C.B., M.P. (the Deputy-Chairman), in reply to a question, stated that negotiations had been pending, the outcome of which would be that, if a small subsidy could be obtained from the British Government, a telegraph cable would be laid from Singapore to Borneo. The proposal had been laid before the Colonial Office, who were in favour of it, but it remained to be seen what the Chancellor of the Exchequer would do. The point that had been urged in favour of the Government helping them was that a line would thus be secured to Hong Kong entirely in connection with British soil. By laying a cable *vid* Borneo, the necessity of going to Saigon in order to get to Hong Kong would be avoided.

Dundee.—A special meeting of the Town Council, Police Commission, and Gas Commission was held, on Friday last, for the purpose of considering the question of electric lighting of the city. The Electric Lighting Committee reported that they had discussed Dr. Hopkinson's report, and had been further advised on the subject by Prof. Ewing. The alternating-current system, with transformers, is, in Dr. Hopkinson's opinion, the best if the gas works are selected for the station. The plant, he thinks, should be able to supply 30,000 watts, or 5,000 lamps of 60 watts each; and he estimates the total cost at £24,726, the annual charges for a plant of 5,000 lights being £5,026 11s. 6d. The corresponding cost upon the three-wire system—the station to be within the area to be supplied—is also fully detailed, the total for conductors and distributing mains being estimated at £19,047, the current charges being estimated at £4,360. After a lengthy discussion, it was decided that in order to maintain the *status quo* and secure the position of the public, a Bill, and also a Provisional Order, should be deposited by the Gas Commissioners and the Police Commissioners to obtain all necessary power, leaving over for after consideration the particular body which should take the power, and that it should be remitted back to the Joint-Committee to collect, mature, and report further information and details.

City and Guilds of London Institute.—On Tuesday night Sir H. Roscoe, M.P., presented the prizes and certificates to the students of the City and Guilds of London Institute at Goldsmiths' Hall, Foster-lane, E.C. There was a large attendance. Amongst those present were the Lord Mayor, who presided, Sir R. Fowler, Sir S. Waterlow, Sir P. Magnus, Sir F. Bramwell, Profs. Ayrton, Gladstone, and Unwin. Mr. W. S. Prideaux (hon. secretary) read a short report on the work of the central institution during the past term. Mr. J. Watney read a report on the work of the Finsbury Technical College, and Prof. Thompson read out the list of awards. Sir H. Roscoe, after distributing the prizes, observed that the Technical Instruction Bill had materially changed the whole aspect of affairs, and sooner or later a complete scheme for technical education would have to be framed. The beginning of such a scheme had been made by the efforts of the City of London Institution, which, with its many branches, was a nucleus of such a system, the importance of which would only be recognised when the history of that important movement came to be written. It was, however, not only necessary to educate the craftsman; his employer needed it equally, if not more. He thought that the Council of the Institute had fully recognised that fact at their central institution. The public should not imagine that the establishment of a larger number of Polytechnics which had recently been founded was the only goal to be aimed at in higher technical instruction. They could not too clearly understand that whatever success attended the foundation of these metropolitan Polytechnics, the work of the centres of higher technical education still remained

MAGNETISM IN IRON AND OTHER METALS.*

BY PROF. J. A. EWING, F.R.S.

I.

§ 1. **Introductory.**—In the series of articles of which this is the first, it is intended to give some account of what experiment has taught about the magnetisation of iron and other members of the magnetic family of metals, with special reference to recent work. The subject has advanced so fast and so far during late years that the text-books have scarcely kept pace with it. Thanks to the labours of Stoletow, Rowland, Hopkinson, and many others (for in so wide a field it would be easy to name a long list of workers), our knowledge of the magnetic qualities of iron has been so much extended that it may fairly be said to deserve a text-book to itself. There are probably many students to whom something of this kind would be of service. At present anyone who wishes to gain a little more information than is given in the somewhat meagre notices which the subject receives in current text-books, has no resource but to explore a large number of more or less bulky and inaccessible original memoirs. If the student aims at thorough knowledge, or if his purpose is to trace the matter historically, nothing could be better; but the quest is long and sometimes not a little wearisome. At the same time the practical bearing of the subject, in relation, especially, to the action of dynamos and transformers, forces it upon the attention of many who have not much time or taste for that method of study. The writer hopes that he may meet a want on the part of general students of physics, as well as on that of practical electricians, when he endeavours to set forth the principal results of experiment on the magnetisation of iron in a connected and in an elementary manner, without either undue brevity or excessive detail. To those who have followed what has lately appeared in original Papers on this subject, he does not expect to have anything new to tell.

Before proceeding to speak of experiments and their results, it may be well to recall the various conventions according to which magnetic quantities are expressed. Most of this introductory matter is, of course, familiar to the student, but parts of it are, perhaps, less familiar, and some confusion is apt to be felt on account of the variety of ways which one may follow in stating facts about magnetic quality. The magnetisation of an iron bar, for example, may be specified by its magnetic moment, by its intensity of magnetisation, or by its magnetic induction; and its readiness to be magnetised may be measured either by what is called its magnetic permeability, or by another not quite identical quantity called its magnetic susceptibility. The student is liable to feel that there is an *embarras de richesse* in magnetic ideas and phraseology. The various lights in which the magnetism of a piece and its magnetic quality may be regarded are, of course, consistent with one another, and are related in a simple enough manner. Some forms of expression have the advantage that they fit in best with modern conceptions of the magnetic state; others survive because they are more convenient in special cases. The magnetic circuit of a dynamo is most simply treated by using one set of terms; another set of terms come readier to hand when we have to speak about the properties of a magnetised steel bar. The student will, therefore, do well to master the meaning of all the magnetic terms in common use, and should accustom himself to look at magnetic phenomena from various points of view.

§ 2. **Magnetic Poles, Axis, and Moment.**—An old and still useful way of looking at the matter is to think of the action of a magnet as due to the existence of two quantities of hypothetical magnetic substance, or "free magnetism," equal in amount and opposite in kind, which are distributed in the neighbourhood of the two ends. These hypothetical positive and negative substances have the property that two portions of like kind repel each other, and two portions of unlike kind attract each other, with a force which is proportional to the product of the amounts of the portions, and inversely proportional to the square of the distance between them. In an ordinary bar magnet the free magnetism is distributed partly over the surface at and near the ends of the bar, and partly throughout the interior of the bar, especially near the ends. The action of the magnet upon anything at a considerable distance from it will be much the same as if the free magnetism were concentrated at two points, near the ends, which are called the *poles*. Strictly speaking, there are no precise poles in a magnet—that is to say, there are no two points at which we might imagine the positive and negative free magnetism to be gathered, and find the magnetic action in external things to be quite unchanged. It is only when the bar is very thin and uniformly magnetised (§ 7, below) that we come near to realising the idea of two definite centres of force at the ends of the bar where the positive and negative free magnetism is concentrated. The idea of poles in a magnet has therefore to be employed with much caution, but it is too useful to be altogether abandoned.

The *strength* of a pole is the whole amount of magnetism which is to be taken as gathered there. *Unit pole*, or unit quantity of free magnetism, is that quantity which repels or attracts another quantity equal to itself with unit force when the two are placed at unit distance from each other. It is now a universal practice to express magnetic quantities in terms of the centimetre-gramme-second system of units. We may, therefore, define the unit pole as that which acts on another pole of equal strength with a force of one dyne when the two are placed one centimetre apart. The *axis* of a magnet is the line joining its poles. The *moment* of a magnet is its pole-strength multiplied by the distance between the poles. According to this conception of a magnet, the magnetic action of the bar is due to the free magnetism at the poles; the middle portion of it is neutral, and merely serves to hold apart the ends, in which the free magnetism resides.

§ 3. **Magnetic Field and Magnetic Force.**—For many purposes this conception is a very serviceable one. It is especially

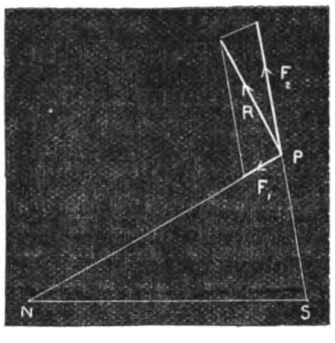

FIG. 1

serviceable when we have to treat of the influence which the magnet exerts throughout the space in its neighbourhood, or throughout what is called the *magnetic field*. To examine the magnetic field, we may think of the force which the magnet N S (Fig. 1) will exert on an imaginary particle of magnetic substance, P, placed anywhere in its neighbourhood. The two poles of the magnet will exert two forces, F_1 and F_2, which are proportional to $\frac{1}{(N P)^2}$ and $\frac{1}{(S P)^2}$: one pole will tend to pull the particle towards it, the other pole will tend to push the particle from it. These forces will have for their resultant a single force, R, which is the whole force exerted by the magnet upon the particle. The direction of this resultant is definite at any point in the field, but its amount will depend on the amount of magnetic substance in the particle. Suppose, now, that we take a particle in which the amount of magnetic substance is one unit (as defined in § 2), and observe the force exerted upon it when it is placed anywhere in the field, we now find a force definite (at any one point of the field) both in magnitude and direction. This force measures the intensity of the field at the point in question, and is called the *magnetic force* at that point. Instead of one magnet only there may be any number of magnets, the poles of which contribute to the production of magnetic force at any point of the

*All rights are reserved.

Digitized by Google

field in which the magnets lie. We may still think of each pole as exerting its own component of force on the imaginary particle of unit strength, and then combine all these components to find a single resultant which measures the magnetic force.

Electric currents also give rise to magnetic force in their neighbourhood, so that, in considering the value of the magnetic force at any place, we have to take their action into account as well as the action of the poles of neighbouring magnets. But whatever current or magnets contribute to the production of the magnetic field, the magnetic force at any point of space has a definite direction and value, which may be expressed by stating the mechanical force which would be felt by a unit magnetic pole when placed there. The direction of the magnetic force is the direction in which the unit particle

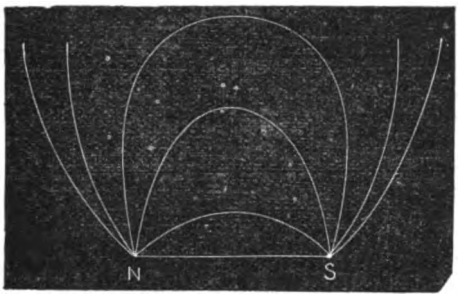

Fig. 2.

will tend to move, and the value of the magnetic force is the value in dynes of the mechanical force which tends to move the particle.

§ 4. **Lines of Magnetic Force.**—If we allow the particle to move so that the direction it takes is, at every instant, the direction in which the magnetic force acts upon it, and if we mark the course it takes through space, we shall trace out what is called a *line of magnetic force*. In general these lines are curved, for the direction of the magnetic force varies as we pass from point to point through the field. If the magnetic field is produced by a single pair of opposite poles, the lines of force start from the south pole and spread in curves, which bend round through space, and all

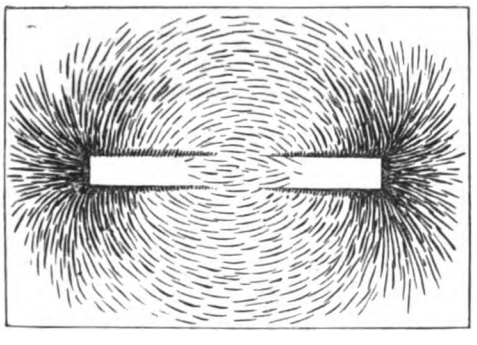

Fig. 3.

converge on the north pole (Fig. 2). The well-known curves in which iron filings group themselves when scattered near a magnet represent approximately the forms taken by the lines of force. In the field produced by an actual bar magnet (Fig. 3) the lines do not converge as in Fig. 2 to a single pair of points, for the positive and negative quantities of free magnetism are each distributed over a considerable part of the length of the bar. Where the lines come close to one another the magnetic force is intense: where they lie far apart the field is weak. If we pass along lines of force from one place to another in the magnetic field, we shall find that the intensity of magnetic force at each place is proportional to the number of lines of force which cross an imaginary surface of unit area, placed there and set so that it stands at right angles to the direction of the lines. We can make the number of lines which cut such a surface not only proportional, but numerically equal to the magnetic force throughout the whole field, by adhering to a proper convention as to the whole number of lines to be drawn. The convention is that the number of lines of force which start from any pole of strength m is $4\pi m$. Consider a sphere of radius r in centimetres enclosing a magnetic pole of strength m. According to the convention, the number of lines of force which radiate from the pole and cut the surface of the sphere is $4\pi m$. But the area of surface of the sphere is in square centimetres $4\pi r^2$. The number of lines of force per square centimetre at the surface of the sphere is therefore $\frac{4\pi m}{4\pi r^2}$, or $\frac{m}{r^2}$, and this is also the measure of the magnetic force there, for the force is due to a pole m at a distance r.

§ 5. **Uniform Magnetic Field.**—In a uniform field—that is to say, a field in which the magnetic force has the same direction and the same intensity at all points—the lines of force are straight, parallel, and equally spaced. The magnetic field due to the earth's action as a magnet is sensibly uniform throughout any small space, such as that of a room. Good approximations to a uniform field can be obtained by suitable arrangements of magnets, or of conductors carrying electric currents. Thus, if we take a long uniform solenoid or helix of wire, wound so that the diameter is constant and the number of turns is the same in each unit of the length, and pass a current through it, a magnetic field will be produced which is very nearly uniform throughout the whole space within the solenoid, except close to the ends. The value of the magnetic force in this field due to the current is $4\pi C n$, where C is the current in absolute electro-magnetic units, and n is the number of turns in the winding per centimetre of the length of the solenoid. Reducing this to practical units, the magnetic force within the solenoid is 1·257 times the number of ampere-turns per centimetre of the length.

Again, a nearly uniform field may be produced by taking two similar magnets with flat ends and placing them in line with their flat ends parallel, so that the north pole of one nearly touches the south pole of the other. In the narrow gap between the ends facing one another there is a strong magnetic field, through which the lines of force pass straight across from one face to the other. The field is very nearly uniform except at the edges.

(To be continued.)

THE KEELEY SYSTEM OF WORKING TELEGRAPH CIRCUITS.

We have recently had brought to our notice a system of working telegraph circuits, devised by Mr. D. H. Keeley, of Ottawa, which is claimed to be an improvement on existing methods; and, as the matter is one of importance, especially to those concerned with the working of submarine cables, we give below a description of the arrangement proposed.

After setting forth the effects of static charge and discharge, due to the electrification of the conductor, on the transmission of signals in a telegraph circuit, the inventor states that his object is to remove this impediment, and to render the transmission of signals, both in single and duplex circuits, on aërial or submarine wires of the greatest length, practicable at the highest rate of speeds. This he claims to accomplish by the simple expedient of applying a rapidly reversing current at the receiving end of a line worked by a double-current transmitter and using polarised receiving instruments. When the sending-key is depressed, a current of one polarity, say +, goes to line. If the current-reverser at the distant end presents a − current to line, that current combines its effect with that of the − current transmitted and affects the polarised relay in one direction, say closes it. When, however, the current-reverser presents a + current to line, its effect is neutralised by that of the + current transmitted, and the receiver remains closed. If the key at the sending station is upraised, a − current is transmitted and combines with the current presented to line by the

Digitized by Google

current-reverser; should it be +, moving the polarised receiver in the direction opposite to its movement before, and opening it. Should the current at the receiving end, however, be −, it is neutralised by the − transmitted, and the receiver remains open. Hence the distant receiver is actuated by the distant battery under the operation of the sending key.

The annexed figure shows the application of the system to cable circuits worked by double key, where signals are effected by right and left deflections of a galvanometer needle produced by current impulses of dot length uniformly, + representing dots and − dashes. The object sought is to obviate the increased charge of the cable which would attend the longer depression of the key in signalling a dash on the Morse system. In order to effect a partial neutralisation of the residual current which gradually discharges from the cable after the signalling current is withdrawn, the receiving instruments have hitherto been placed, through the medium of a condenser, in circuits secondary to those in which the transmitters operate. This arrangement involves the introduction of great resistance between the cable and the earth at one end of the circuit, preventing the rapid discharge of the cable, causing a sluggish movement of the receiving instrument, and hindering rapid signalling. It is well known that the effect of the residual current can be partially neutralised by the presentation of a reverse current to line at the transmitting end, immediately on the withdrawal of the signalling impulse; and the diagram shows how this result, which has not hitherto in practice been efficiently attained, is sought to be secured under Mr. Keeley's system. The condenser and secondary circuit are dispensed with, and the double-current keys arranged to transmit automatically the alternate impulse in their movement from the under to the upper contact, after the signalling impulse has been sent into the cable.

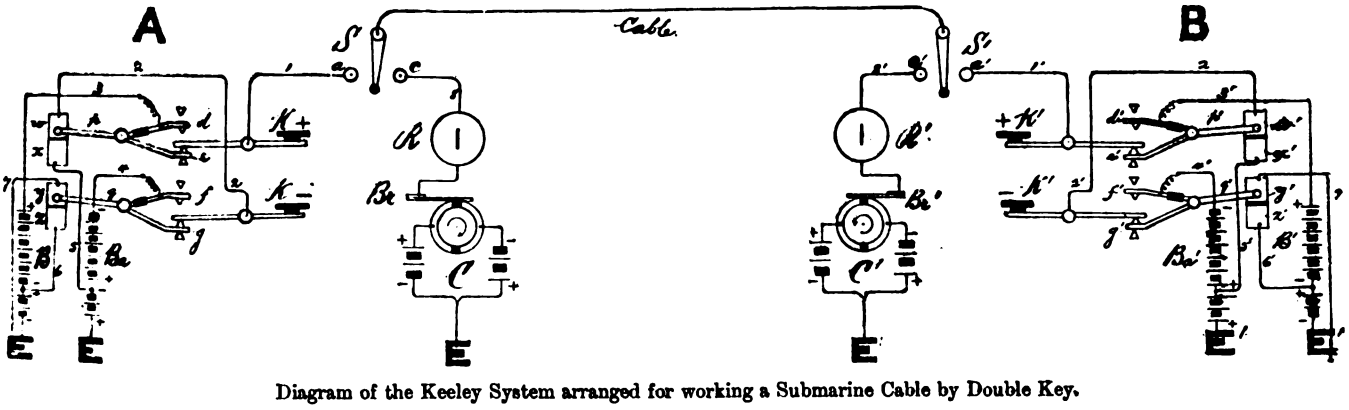

Diagram of the Keeley System arranged for working a Submarine Cable by Double Key.

In the figure S at station A is a three-point switch, to the arm of which the cable conductor is directly connected. When S is on the point *a* the cable is connected with the transmitting keys, and when S is on the point C the cable is connected with the receiving instrument. The keys K + and K − when depressed send currents from the batteries B and B *a* respectively. The key K + plays between jaws *d e*, from whose arbor a spring extension, *p*, presses against flat contact plates, W *x*; the friction contact thus created holds the jaws *d e* in whatever position moved by the rear arm of the key; the contact on the jaw *d* is insulated from the jaw *e* and extension *p*; the jaw *e*, and extension *p* are in electrical continuity. The key K − is likewise associated with jaws, *f g*, extension, *q*, and contact plates, *y z*. R' is the receiving galvanometer or syphon recorder whose deflections to right and left represent dots and dashes. C is the commutator or current alternator already described. The arrangements at station B are precisely similar, and the parts are correspondingly lettered.

Suppose the switch S at station A is put on the point *a* and the switch S' at B is put on the point *c'*, then A will be in position to send to B; and, in the normal condition, both keys being upraised at A, the circuit will be from E at A, by wire 7, plate *y*, extension *q*, jaw *g*, key K −, wire 2, plate *w*, extension *p*, jaw *e*, key K +, wire 1, point *a*, arm S, to cable, thence by switch S', at B, point *c'*, wire 8, through receiver K', brush B *r'*, alternator C', to earth at E. There is in this case no battery in circuit at the sending station A, while at the receiving end B the commutator C' is alternately presenting + and − currents to line through the receiver K'. These currents, rapidly succeeding one another, have the effect of oscillating the recording needle of the receiver K' within narrow limits.

Now if the key K + at station A is depressed, the following action occurs. The rear arm of K + leaves the jaw *e*, and striking the jaw *d*, moves it to its limiting stop. By this movement the extension *p* is shifted from the plate *w* to *x*. While the key K + is in contact with jaw *d*, the + current from the battery B goes to line, the circuit is from E to B −, from B + by wire 3 to jaw *d*, key K + to line, thence through the receiver R' at station B, alternator C', to earth at E. The + current now proceeding from A, combines with the − from the alternator C' at B, and deflects the recording needle to one side, say the right, signalising a dot. The + current from A opposes the + from the alternator C' at B; hence this latter current is neutralised in its normal effect in the receiving instrument. Meanwhile, the key K + at station A is upraised, the rear arm leaves the jaw *d*, withdrawing the + current from the line, and passes down towards the jaw *e*; a discharge from the line follows. The part that goes to earth at station B is opposed and neutralised by the first + current emanating from the commutator C' at that end; this neutralisation of the discharge is further facilitated by the transmission of a momentary reverse current from the distant end, as will presently be explained, and the needle of the receiver promptly returns to its normal limit of oscillation. Meanwhile, the rear arm of the key K + at station A strikes the jaw *e*, and moves it down to its limiting stop; during this operation, however, a − current is momentarily presented to line. When the rear arm of K + touches the jaw *e*, the extension *p* is still on the plate *x*, which is connected to a point low down in the series of the battery B *a* −. In this condition the circuit is traced from E through part of battery B *a* + by wire 5, to plate *x*, extension *p*, jaw *e*, key K +, to line. A weak − current is, therefore, presented to line; it is, however, only momentary—the movement of the rear arm of K + carries the jaw *e* down to its limiting stop, and shifts the extension *p* from the plate *x* to *w*, whence the circuit is traced, as in the normal condition, to earth.

It will be seen by the drawing that the key K − is in the same way connected with the batteries B *a* − and B +, so that the depression of K − sends the full current of B *a* − to line; and when it rises, a weaker current, emanating from a portion of B +, is sent to line. The object of this device, as already explained, is the presentation of the weak alternate current, which, combining with the return current following the withdrawal of the previous signalling one, contributes to the neutralisation of the discharge from the distant end, as it occasions a concurrent flow of electricity in the opposite direction in the circuit. The consequence is that the movements of the recording needle to the right and left at the distant end can be more rapidly produced and more sharply defined for each successive signal than has been possible with the circuit arrangements and devices heretofore employed in double-key transmission.

Mr. Keeley's system is a very ingenious attempt to improve

Digitized by Google

the working of submarine cables, but we do not think it will be found to contain the elements of practical success. Although, as a whole, it has never, so far as we know, been tested before, some of the arrangements have been tried in various ways without offering any advantage, or, indeed, being equal to the present methods of signalling. It would seem that Mr. Keeley has not had practical experience of the working of long submarine lines, or he would have known, for instance, that it is out of the question to use polarised relays. A feature is made of the claim that the arrangement described would do away with the necessity for condensers, but, as a matter of fact, they are found to render the signals more distinct and reduce the effects of earth currents to a minimum, and are used at both ends of the line.

Inventors seem frequently to assume that retardation on submarine cables can be overcome, but it is no more likely to be entirely eliminated than friction or gravity. We happen to know that a system similar to Mr. Keeley's in other respects—of sending rapid reversals through a cable from the transmitting end—has been quite recently tried, but with an entire absence of success.

THE INSTITUTION OF ELECTRICAL ENGINEERS.

"Electrical Engineering in America."*

BY G. L. ADDENBROOKE, ASSOCIATE.

(*Concluded from page 149.*)

CENTRAL STATIONS.

The next station I visited was that of the Westinghouse Company, at Pittsburg. It is situated in a large building of the warehouse type, quite in the centre of the town. The boilers here are of the water-tube type, but heated by natural gas instead of coal. This natural gas is brought in pipes to the town from a distance of 35 miles. The company who own the line of piping—of which, by the way, Mr. George Westinghouse is also President—sell this gas to manufactories, &c., at a rate which is nearly equivalent to the cost of coal; so that, although the convenience is great in using it, the economy is not so large as might at first be anticipated. Work at the Pittsburg station was in the first instance begun with two Corliss single-cylinder engines of the ordinary type, driving on to a line of countershafting; but this method of working has not been extended, and one of these engines has since been removed. The next additions to the station consisted of Westinghouse Standard engines of 250 indicated horse-power, driving 2,500-light alternating dynamos. These engines stand on square blocks of concrete or masonry; the blocks for this size engine are about 7ft. by 5ft. The last additions are of the new type of Westinghouse Compound engine. From a power point of view, as well as from an electric lighting point of view, the station has therefore something of historical interest.

While in Pittsburg I had an opportunity of going carefully through the Westinghouse engine factory with Mr. Ralph Bagaley, the vice-president and manager, and of seeing all the details of construction of each of the different types of engines. The Westinghouse Company make three styles of engine, each worked by a piston valve and single eccentric. The Standard type is so well known that I will not say anything about it. In it, as you are probably aware, the steam valve is between the cylinders, and set at a slight angle to them, while the cylinders are set rather over their work, and not directly in a vertical line above the crank shaft. The Junior and the new Compound engines are on somewhat different lines to the Standard, while the main principles involved are nearly the same. In these two later types the piston valve lies horizontally along the top of the cylinder heads. It is operated by a single eccentric working outside the engine case in a vertical direction, the motion being changed to a horizontal one by means of an L piece attached to the engine case by a hinge. The whole movement is of simple character, and works exceedingly well. In fact, there are practically no more working parts in the Compound engine than in the Junior or the Standard two-cylinder patterns, and the one is as simple as the other. The Standard type has now stood the test of several years' work very satisfactorily, and there is no room to doubt that the compound engine, constructed in the same shops and by the same method as the Standard engine, will wear at least as well. The makers' tests show exceedingly good results for this compound engine, viz., from 18½lb. to 19½lb. of water per brake horse-power hour with condenser, and from 24lb. to 25½lb. without condenser. I saw the testing apparatus in the makers' shops, and engines undergoing their test preparatory to delivery, and feel perfectly confident that the figures given by the makers are thoroughly reliable. I will not describe this engine more fully, although to do so would probably elicit an interesting discussion, as it would be wandering from the subject of my Paper. On the other hand, the remarks I have made are not intended to compare the Westinghouse compound engine with any other engine of at all similar type, but rather to draw the attention of electrical engineers to the fact that there are now, at any rate, two large firms of the highest repute turning out this class of engine, and ready to guarantee economy and efficiency on a par with Corliss engines.

Returning to the Pittsburg station, five Westinghouse engines of 250 indicated horse-power drive five alternating-current dynamos of 2,500 16 candle-power lights capacity each, besides the machine driven from the Corliss engine. The exciters are run from smaller engines. The engines driving the alternating dynamos make 250 revolutions per minute, the dynamos making 1,050 revolutions per minute. The power is conveyed overhead by belts to the first floor, where the dynamos are placed. Each of these dynamos is on a sliding bed, so that the belt can be tightened, and, as I have already said, the exciters are run separately from the machines. The machines are so well known it is hardly necessary to describe them. I may, however, perhaps with advantage say a few words on the construction of the armature, which is the least easy part to understand from written descriptions or diagrams. In Prof. Silvanus Thompson's book on dynamo machines the diameter of the armature is given at nearly twice its breadth. While this is true of the smaller machines, in the 2,500 machine—which is the standard size for large stations, and is the size employed in the new station in Sardinia-street, in London—the length of the drum is considerably greater than the diameter. The drum itself is formed of thin iron plates, just like an Edison armature, only of larger diameter; and as the iron near the centre is useless, holes are punched in the sheets, which lightens the armature and secures ventilation. Round the outside of this iron core, and over the two ends, insulation is laid. As regards the coils of wire in which the current is generated, they are made in this way:—Beginning at the inner side of the coil, the wire is wound on an oblong frame to correspond with the shape of the field-magnets, one turn on the top of the other. The coils are only one wire thick—that is, there is only one layer of wire between the drum and the field-magnets. When these thin flat coils are laid on the drum, the round ends of the coils are turned down at right angles over the edge at each end of the drum, and the connections from coil to coil are made. A small piece of wood screwed into the side of the drum, and projecting over the end of each coil, keeps it in its place. When all the coils are fixed in their places, sheets of mica are laid over them all round the armature, and bands of fine wire with a little thicker insulation underneath them are bound round the whole armature at short intervals, in exactly the same way as is usual with the armatures of continuous-current machines. An armature made in this way has perhaps rather an amateurish look about it, but there is no doubt that they work well in practice and give excellent results. It is further worth noting that as the field-magnets are long and narrow—a ratio of at least 10 to 1 in the large machines—they cannot be very economical as far as exciting current is concerned. Still, since the exciting current, anyhow, bears such a small ratio to the energy which the machine will transform into electric current, this is not a very material point. The mains are run from the dynamos to the switch-board in troughs cut in the joists supporting the floor, which is made to take up over these troughs. The switch-board at Pittsburg consisted of a wooden frame boarded over, about 9ft. high and 12 or 14ft. long, and standing about 3ft. from the wall, so as to give room to go behind and make the connections. This, I may say, is the usual way of arranging switch-boards in America.

The general type of switch used in America for alternating-current work—and it is not confined to the Westinghouse Company—is exceedingly simple in construction and operation, as well as efficient. In general principle it is like an ordinary tobacco chopper. To the top of a small upright a lever is hinged, terminating in an insulated handle. The metal part of this lever has a hatchet-shaped projection cast on it, projecting in the same plane as the motion of the lever. When the lever is pulled down the hatchet-shaped piece sticks in between two spring pieces set up to receive it, and so makes contact. If the lever has two hatchet-shaped pieces attached to it opposite each other, and engaging in spring pieces on either side, according as the handle is thrown over in one direction or the other, we have a two-way switch. Unite two of these levers together by a cross-bar of insulating material, with a handle in the middle, and we have a double-pole two-way switch. Place a spring in the columns holding the hinges on which the levers turn, to throw down the levers when nearing the spring contact-pieces on either side, and we have the complete article.

* Paper read before the Institution of Electrical Engineers, November 28, 1889.

Digitized by Google

These switches were all mounted on wooden bases. In fact, I saw no slate used in America anywhere for such purposes, except at the Electric Club in New York. In the new Westinghouse Station in Sardinia-street, however, the whole of the switches are mounted on enamelled slate, and very nice they look.

One exciter is used for several machines; each exciter has a resistance in its field-magnets, which can be varied. There is, moreover, a separate resistance in the field-magnet circuit of each alternating machine, so that the E.M.F. of the machine can be varied while its speed remains constant. Double throw-over switches are connected so that each alternating-current machine can be connected to either of two exciters, and so that any main circuit can be run from any machine. The general principle followed is to keep the machines at work as fully loaded as possible. Thus in the day many circuits will be run off one machine, but as evening comes on they will one by one be taken off and put on other machines. The throwing over is so quickly done as to only just cause a perceptible flicker in the lights. All these switches were bare and unprotected. I did not hear or see much of the method of running two separate machines parallel on the same circuit. Whatever may be done in isolated instances, it does not appear to be practised generally; indeed, with the American system of running a number of small circuits instead of fewer heavy ones, the desirability of doing so does not often come in.

I should like to endorse here what I see Professor George Forbes said in his Paper on foreign central stations with regard to feeders. The area which can be economically supplied from a central station has certainly been greatly increased by the adoption of 1,000 or 2,000 volts instead of 100. But at the same time our notions of the area which can be supplied from one centre have experienced a corresponding growth. If, then, such an increased area is supplied on a high-tension system from one centre, we have as great, or nearly as great, falls of potential to deal with as if the low-tension system were used over a correspondingly smaller area. To secure the highest class of lighting, therefore, together with the flexibility desirable in an installation lighting a large area, the whole of the outside work should be based on as complete and carefully designed a set of feeders as from our present knowledge we should employ with a low-tension system. On many of the Westinghouse feeders lighting at great distances, there is a fall of potential of as much as 10 per cent. To avoid pilot wires an indicator is used, which, I think, Professor Forbes has already described here. There is no regular voltmeter for driving the machines by, but an indicator is used with but one single mark on the dial. When the machine is giving the voltage which is required at the further end of the feeder to keep the lamps at their proper brightness, the hand of the indicator will be right over the mark on the dial. The loss in the feeder will, of course, differ according to the current flowing through it, so, to allow for this, a compensator is attached to the indicator. The main current flows through the compensator, which is arranged to cause a slight back-pull on the needle of the indicator: this pull becomes greater as the current increases. As the current increases, therefore, a slightly higher voltage on the machine will be necessary to keep the needle in its place. The instruments have, of course, to be made so that they can be adjusted to the calculated requirements of each feeder. When once set right, however, their operation is simple enough. The Westinghouse Company also use a piece of apparatus containing an adjustable converter, which enables them to supply current from the same machine to two feeders having a different fall of potential.

The Thomson-Houston Station in New York is situated in Twenty-fourth-street East, near the river, and occupies what was formerly a large sugar refinery. It is, therefore, a building of the warehouse class, but very strongly built. I was told that this station was neither so large nor so well-arranged as their station in Brooklyn, but the latter, I regret, I had not time to see. Two boilers struck me here as out of the ordinary patterns. The simplest way to describe them is, I think, to consider them as large locomotive fire-tube boilers set on end. The tubes are about 15 feet long, and the water-line is about 10 feet up the tubes. This gives a considerable steam space above, through which the fire tubes pass, superheating the steam generated, and thoroughly drying it. At first sight one might suppose this an uneconomical pattern, as the heated gases pass so quickly into the flue. But the gases appear to give out their heat well, for Mr. Foster, the station superintendent, told me the temperature of the gases going into the flue was not above 550 degrees Fahr. The lower portion of this boiler is, however, the interesting part. I cannot very well describe it without the aid of a diagram. The outer shell of the boiler is expanded out and prolonged about a couple of feet below the tubes. It is turned up at the bottom, and united all round to the crown plate of the boiler, into which the lower ends of the tubes are expanded. This prolongation of the shell then forms a circular hollow, or chamber, about 2ft. deep. The internal space enclosed by this hollow chamber forms the fire-box or furnace, and is about 6ft. in diameter. Any sediment collects in the hollow chamber, and can be taken out at manholes. There were two of these boilers in use, and it was in contemplation to increase their number. The engine—and there is only one—which furnishes power to this station is a large compound condensing Corliss engine; the two cylinders being in tandem. It is a very fine piece of work of its class. It drives on to a large fly-wheel with a smooth face of about 60in. breadth. This fly-wheel transmits its power to a line of countershafting, which is arranged on the floor above, by means of a large leather belt 58in. broad, and of great thickness. I think, in all, 17 machines are run from this line of countershafting—15 55-light arc machines and 2 alternating-current machines; in this case the machines are on the same floor as the countershafting. The general construction of the Thomson-Houston alternating-current machines is on the same lines as those of the Westinghouse Company. The main difference is that instead of the ends of the coils on the armatures being turned over the edge of the core, as in the Westinghouse machine, the armature has a sort of prolonged lip all round the outside at each end, and the ends of the coils lie flat on this instead of being turned over. To their smaller machines, also, the Thomson-Houston Company frequently add a commutator, and commute part of the current to excite the field-magnets, as Messrs. Zipernowski, Deri, and Blathy are in the habit of doing. The switch-board here is on much the same lines as I have already described. It was all quite open and exposed; but I was told that, in view of an accident which had happened there a short time before, they proposed to cover the exposed parts up. This way of leaving the working parts of high-tension alternating-current switch-boards exposed is not confined to American manufacturers: a good deal of the Continental work is even worse. Yet all the different patterns of switches and converters could be protected at a moderate cost, and by the exercise of a very moderate amount of skill and ingenuity. I cannot help thinking that not to do so, to save money in this direction, is false economy.

Isolated Plants.

Let us now turn for a few moments from central stations to what are called "private installations" in this country and "isolated plants" in America. I have already spoken of internal construction work, or wiring and fittings, in connection with central stations. With isolated plants there is not much difference. Of course the character of the work differs greatly in different places, as it does here; but, taking it as a whole, I don't think it is equal to our standard, whether from an engineering or artistic point of view. I noticed, by the way, that there is a much greater tendency to turn incandescent lamps upwards in fittings, like gas jets, instead of downwards, as with us the majority of lamps are turned. Isolated plants are driven by steam and gas engines, located in cellars and basements, exactly like they are here. As you are aware, accumulators are not so generally used: I only saw the set at the New York Electric Club. With respect to dynamos, the Americans have been fully alive to the developments, both theoretical and practical, in our knowledge of the magnetic circuit which have taken place during the last four or five years, and all their modern machines appeared to me fairly up to date in this particular. What I may be permitted to call the Edison-Hopkinson type, the Kapp type, the Manchester type, and the Weston type—the latter with two magnets, placed horizontally—appear to be the favourites, just as they are here. The construction and workmanship of the machines appeared to be much on a par with our own: there is little to choose between in one or the other. As to the way the installations are run, judging by that crucial practical test the look of the commutator and brushes, it is much the same as here: certainly, I think, on the whole, not better. The lamps, as a rule, I did not find any steadier, nor are they kept nearer their proper voltage than they are here. This applies to arc lamps as well as incandescent. There is no magic about arc lamps over on the other side of the water: they are subject to the same vicissitudes and uncertainties as they are here, and do not burn steadier than those in any moderate-sized station here where the appliances are such that the lamps get a fair chance. The switch-boards in these private installations are nearly always mounted on wood, and there is even a disposition to cut things fine in the strength and solidity of these wooden base-boards, somewhat, as it seemed to me in one or two instances, at the expense of efficiency and lasting qualities.

Electrical Tramways.

Such very full accounts have been published of everything that has been done in this direction, that there is really little I can add to them. In the *Electrical World* for October 19th there is published a table of the electrical tramways in actual operation *and under contract* in the United States. The total mileage of both is 1,260 miles, with 1,884 cars, on 179 roads. Of this 716 miles were, it appears, actually being operated by electricity at the date of the return, and 544 miles were under contract. Of this total 21 miles were worked by cars with storage batteries, and all the rest, with

Digitized by Google

the exception of two or three miles, by overhead conductors. Nothing can be simpler than the way these overhead conductors are put up. Two lines of posts, about 20ft. high, are set up opposite each other, one on each side of the street; light steel wires are run across from one to the other; a small iron holding-piece is attached to the centre of the steel suspender, and this holding-piece carries a bare hard-drawn copper wire, along which the current flows, returning by the rails. Where feeders are used they run along one side of the street, and connections are made at intervals with the central wire. The way the conductor is carried round corners is on a par with the rest of the work. Posts are set at the further corners of the street, and from each of these two, three, or four steel wires are run at an angle with each other, meeting corresponding wires run from posts on the inner side of the curve. In this way the wire is made to take the form of part of a rough polygon, while the horizontal and vertical movements of the fishing-rod connector on the car are sufficiently ample to keep the contact wheel on the wire when the car is going round a corner. This method of erection does not look very nice, certainly, but it appears to answer the purpose well. Such work could, I think, be more solidly carried out here for about £70 a mile. In a few places standards with projecting arms placed in the centre of the street have been used for carrying the overhead conductor. If neatly constructed, there is no reason why these should be unsightly, and they can be used for the further purpose of lighting the streets. A great point about these electrical tramcars is the way in which their speed can be varied. They can be run at three or four miles an hour in crowded streets and while turning corners; or in broad roads in suburbs where there is not much carriage traffic the pace can be increased to 16 miles an hour. The cars are stopped very quickly and reversed, and will, of course, run either way on the same track. The companies claim a reduction of 50 per cent. in the cost of working over the employment of horses, putting aside all the extra facilities which the electrically-propelled car gives. A very noticeable point about all electrically-propelled cars is the quiet and gradual manner in which they start and come to rest, and the evenness of their motion while running. In these points they greatly surpass both cables and horses. I took the opportunity of talking with a good many members of the general public in the train and hotels about the working of these cars. There is no doubt that the outside public thoroughly appreciate them and understand their value. At present electrical tramway work is the most "live" branch of the electrical industry in the States, and everyone connected with it was full of buoyancy and hope as to its future prospects. It is really sad to think that, after all the skill and care which has been lavished on electrical tramway work here, it should be dragging along in such a half-hearted and pottering fashion.

While in America, through the kindness of Mr. Lockwood I had an opportunity of going over the telephone exchange system of New York with him, and of seeing the Courtland-street Exchange, which contains more than 3,500 subscribers, and is capable of extension to double that number. I also visited the Western Electric Company's factories both in Chicago and New York, where all the telephonic apparatus for use in the States is made. Although a description of the present state of this industry would properly come under the heading of my Paper, seeing that the Paper has already extended to such length, and that, owing to circumstances, telephony is a matter of comparatively limited interest here, however important in itself, I will not say more about it, but will conclude with a few general remarks.

In the early portion of this Paper I endeavoured to convey an idea of the roughness and crudeness of American outside construction work. After reading over the proofs of the Paper, I do not think I have overdrawn the picture: rather, it is underdrawn, if anything. At the same time, I do not wish it in any way to be understood that American engineers are necessarily rough and untidy in their ideas, and incapable of different work. Besides their electrical plant, the numbers of beautiful tools, crowned by the latest pattern of the phonograph, which came over here from America, point to an entirely different conclusion. In accuracy of workmanship and careful finish, when they consider it suits their purpose, the Americans are our equals, if not our superiors: the difference lies in the fact that our ideas often differ from theirs as to where this accuracy and careful finish should come in. English engineering would hardly dare to appear before its fellow-citizens as the responsible owner and designer of such a terrible eyesore as American outside work is; but the American engineer appears to look at it from a different point of view. It is not his business to think of his fellow-citizens. Each of his fellow-citizens, he considers, is quite competent and capable of taking care of himself. It is the business of the electrical engineer to forward and extend the applications of electricity. If in doing this he does anything disagreeable to his fellow-citizens, it is for them to protest when it becomes intolerable to them, not for him to think of it beforehand. And I would like you to try and think for yourselves, and really feel, the enormous facilities which American engineers have in the past enjoyed, and still enjoy, in extending their business, by simply being allowed to erect open wires everywhere through the streets. Even where wires are now being put underground, they are largely put underground in order to carry on existing work, and to extend it, not merely to take advantage later of what may chance to turn up on the route. Besides this, we have all had it drilled into us by this time that it does not matter how perfect, how desirable, how useful a thing is likely to be, before it can come into general use the public have got to be educated up to it, to see it, and feel its desirability and utility, and its practicability—to understand it each man for himself. Now the American system of overhead wires and cheap line construction, bad as it may be in itself, has from the very first brought electricity home to everybody, right to their very doors, not so much as a luxury, but as a practical desirable factor of everyday life, an attraction to public resorts, and a good advertisement for business. Consequently electricity is in America no more a wonder, but a fact of everyday life to an extent that it is not yet here. Looking at their plant, looking at their apparatus, and looking at the facilities which Americans have enjoyed for extended practical experiments on a large scale, it does not appear to me that their actual achievements, simply from an engineering and scientific point of view, have been greater than ours have, in spite of the apathy on the part of the public and investors with which we have had to contend. Still, the fact remains that they have done more business than we have, even considering the difference in population.

Of what work we have done so far, Englishmen may feel justly proud, and with better times I trust we may still be able in friendly rivalry to show that we are competitors worthy of America's best mettle.

DISCUSSION

The PRESIDENT, in inviting discussion, remarked that a Paper of such interest could not be adequately dealt with in the time then at their disposal, and announced that the discussion would be continued at the next meeting on December 12th.

Prof. FORBES admired the realistic description of electrical work in the United States given in the Paper, and fully endorsed the author's account of American electrical engineering, particularly as regards the rough-and-ready way in which the work was usually carried out. Although this class of work might be necessary for the rapid extension of electric lighting (as well as of railways) in America, where great distances have to be covered, yet he thought the more solid construction adopted by English engineers would prove better in the long run. For some time past he had frequently heard of great advances made on the other side of the Atlantic, and expected to have heard something definite about them from Mr. Addenbrooke, but, with the exception of electric tramways, little change seemed to have been made since his visit two years ago. At that time, however, most tramways were worked by accumulators. Information about motors and meters would have been very acceptable, particularly for alternating-current work. Speaking of American factories, Prof. Forbes said that great attention was paid to testing, and, as a result, the efficiency of converters had been considerably increased. As regards distribution, he was glad to hear of the frequent use of feeders, and hoped they would be more generally adopted in England. In conclusion, he asked what kind of cable was used for underground work.

Mr. H. C. DONOVAN considered that the apparent disregard of insulation was to be attributed to the dryness of the climate, and expected to have seen this brought out in the Paper.

Mr. W. P. GRANVILLE said the usual method of specifying insulation resistance of cables (viz., in *megohms per mile*) was unsatisfactory, and that the diameter of the conductor should be taken into account; for if this were not done, the same material, used on conductors of different sizes, would give quite different insulation resistances. He also thought that the insulation tests of lead-covered cable should be made before sheathing, and whilst the cable was immersed in water. In his opinion the whole subject required reconsideration.

Prof. S. P. THOMPSON had hoped to hear that in the five years since he visited the States, improved methods of wiring, &c., would have been adopted, but no great change seemed to have taken place, excepting in the use of alternating currents. On his visit he obtained an insulator even more crude than the one described by Mr. Addenbrooke. After making inquiries as to the kind of motor used on the constant-current arc circuits, Dr. Thompson expressed his opinion that the alleged greater steadiness of American arc lights was not due to any superiority in the design or workmanship of the lamps, but to the greater personal pride and confidence which the attendants have in the particular system with which they are connected.

Mr. SWINBURNE pointed out the great difference which existed in the management of English and American factories, and thought the system adopted in the latter, where the perfecting of designs and the experimental work are kept quite distinct from the wholesale manufacturing part of the business, was most likely to lead to success. So far, however, he believed machines of English design better than American, for the weight efficiency of the former was generally higher. Referring to Mr. Granville's contention, he said that instead of insulation resistances being given in *megohms per mile*, they should be expressed in *megohm miles* for each size of conductor.

The PRESIDENT, whilst deprecating imperfect work in general, thought it advisable that English electricians should acquire whatever good could be got from the "rough-and-ready" methods adopted in America, and considered that progress might be retarded by waiting too long to

Digitized by Google

attain perfection. He was anxious to know how constant currents were used for motors, and also whether the overhead wires used for tramways interfered with the ordinary street traffic.

Replying to Prof. Forbes' question as to recent advances, Mr. ADDENBROOKE said he had not concerned himself with them, for his object was to see the systems and apparatus in common use. As to motors, he made no inquiries respecting their peculiarities; but as regards meters, he was informed that numbers of the Westinghouse type were in constant use. He agreed with Prof. Forbes about the way in which testing is appreciated, and with Prof. Thompson as regards the interest which the men take in their work: the latter fact he attributed to better wages and greater chances of promotion. Speaking of the insulation of cables, he thought the absolute thickness of insulating material should be stated. In reply to the President's question relating to tramway wires, Mr. Addenbrooke pointed out that they were placed eight or nine feet above the tops of the cars, contact being made by a "fishing rod" connection. In some cases these wires are carried by brackets projecting from poles fixed along the middle of the roadway, the poles being also utilised for supporting arc lamps, and for general lighting circuits.

December 12th.

After the adoption of the Report of the Council, and the passing of the usual votes of thanks, the discussion on Mr. Addenbrooke's Paper, "Electrical Engineering in America," was resumed:—

Mr. LANT CARPENTER, who paid a hurried visit to America during August and September, said he quite concurred in Mr. Addenbrooke's remarks about the temporary character of the work, particularly in the western towns. In many places on the Pacific slope, he found that water power was extensively used, both for arc lighting and for tramway work. One town in Washington, he observed, had laid down electric tramways before making the common roads. Incandescent lamps were comparatively rarely seen in the Far West, and from inquiries he learned that where they had been tried, the stations were so badly managed that the life of the lamps averaged between 200 or 300 hours. Passing on to Canada, he said that Quebec, Montreal, and Ottawa were all lighted electrically by water-power, and in the latter city he was informed that many alternate-current motors of the Tesla type were in constant use. Another fact that struck him was the large numbers of long-distance telephone wires in use in the States. He also noticed that many of the wires were now being put underground.

Mr. G. S. RAM said he could not agree with Mr. Addenbrooke on the glaring character of arc lamps fixed on poles. He greatly preferred the blaze of light in that city to the comparative darkness of London. As regards the character of overhead work, he thought the account given in the Paper was not overdrawn, and in support of this he exhibited a photograph of a building in Broadway, New York, in which hundreds of wires were unintentionally included. On careful examination of the photograph the insulation on some of the wires was seen to be hanging in shreds.

Mr. C. E. SPAGNOLETTI thought the necessities for insulation were so different in England and America that the systems could not be compared on the same basis. To show the great variation of insulation resistances in this country, he said that on the South Wales Branch of the Great Western Railway, the insulation resistance of the telegraph lines varies from several meghoms to a few thousand ohms, according to the weather. He also mentioned the difficulties experienced by Mr. Edison when experimenting in London and at Ealing with his Automatic Chemical Telegraph. The maximum rate he could attain here was 500 words per minute, whereas in America he could get 2,000.

Mr. PREECE, speaking of insulation requirements in the two countries, said that in his opinion the differences arise from the fact that the prevailing winds here are warmed and moistened by passing over the Gulf stream, whilst in America, the shores being washed by polar currents, the winds are cold and dry. Referring to his own visits to America, the speaker said he always benefited considerably by being associated with the "go-aheadedness" of American engineers, and he believed that on visiting this country American engineers derived similar advantages.

Mr. CROMPTON said the Paper deserved a good deal of study, and there were some points upon which he desired further information. For example, the method of preventing vibration mentioned would, if effective, be of great importance, for one would have expected such an arrangement to increase rather than diminish vibration. Judging from the remarks about regulating resistances, he would infer that in this respect America was behind European practice, for on this side of the water such resistances had been done away with. The fact of alternate-current machines not being usually run in parallel (as attested by Mr. Addenbrooke), tended to confirm his (Mr. Crompton's) statements made in his Paper on "Central Station Lighting," read in April, 1888. As regards the boilers described in connection with the Thomson-Houston station at New York, he thought such a design would not be tolerated in this country, for the upper parts of the tubes were liable to get overheated and collapse. Speaking of tramway work, Mr. Crompton said American engineers had been greatly favoured by being allowed to erect overhead wires anywhere and anyhow, but he was afraid such facilities would never be granted in England.

Mr. A. RECKENZAUN deprecated the wholesale condemnation of posts made by Mr. Addenbrooke, and said that many were not unsightly, whilst some were ornamental. He considered the Paper chiefly a criticism of the bad work done in America, and the good work was barely mentioned.

Mr. F. RECKENZAUN concurred in his brother's remarks about the unfair criticism contained in the Paper, and thought the differences of opinion arose from the totally different ideas as to the way in which electrical engineering should be carried out. In the American methods, he said, great skill and ingenuity were shown in combining economy with simplicity and efficiency. Although the arc lamps were not ornamental, yet they were simple and efficient, and their cheap construction admitted of their being universally used. He agreed in general with Mr. Lant Carpenter's remarks on incandescent lighting, but was inclined to believe its limited use was due to the people wanting the biggest and best light obtainable at the price.

Mr. ADDENBROOKE, in reply to Messrs. Reckenzaun, said he had specially mentioned in his Paper that the Thomson-Houston Company were putting up work much better than the average, and as to posts, he was glad to say the tramways companies were making considerable improvements. The arrangement of flooring referred to by Mr. Crompton was not intended to diminish vibration, but to prevent such vibration being transmitted to the brickwork. As regards the boilers criticised by the same speaker, he (Mr. Addenbrooke) could only say that those in charge of them informed him that it was intended to have more of them. It was not his intention to criticise all American electrical engineering in a hostile spirit, for he thought there was little difference in the capacity of English and American engineers. The necessities, however, of the two countries were entirely different, and each had to adapt himself to his own surroundings. The motors used on the arc circuits were, as far as he could learn, simply series ones provided with switches for cutting out parts of the magnet coils. In concluding, Mr. Addenbrooke said he had the opportunity of conversing with many of the American engineers who visited this country in the summer, and all were greatly pleased with the kind and courteous manner in which they were received.

After the thanks of the meeting had been given to the author for his Paper, Dr. S. P. Thompson directed attention to some American blue glass insulators, which he had brought for inspection, and remarked that in a recent American work on electric lighting, which was now being circulated in this country, these insulators are recommended as suitable for almost any purpose.

Mr. Addenbrooke also exhibited a piece of the cable used in underground work in New York, the chief point of interest being the hardness of the insulating material employed.

ON THE LEAKAGE OF NEGATIVE ELECTRICITY CAUSED BY SUN AND DAYLIGHT.*

BY T. ELSTER AND H. GEITEL.

In reference to the theory of atmospheric electricity propounded by Arrhenius,† we have recently made a series of experiments to ascertain whether sun- and daylight have the property of gradually withdrawing the charge from negatively electrified bodies. M. Hoor‡ alone has established such an action, while all other observers, so far as we know, have not been able to discover any. We have therefore been greatly surprised to find that not only sun- but also ordinary diffused daylight can under suitable conditions rapidly discharge a negatively electrified body.

A zinc dish, 20 centim. in diameter, is exposed in the open on an insulating support in such a manner that it is not acted on by negative electricity, and is put in conducting communication with a quadrant-electrometer, or an Exner's electroscope, and further, is so arranged that the dish can be put in the dark or light at pleasure. The following phenomena can then be observed, which, it is true, are already known from experiments on ultra-violet light. The dry dish polished with emery completely loses a negative charge of 300 volts in 60 seconds: an equally high positive charge is retained. The loss of the negative charge ceases as soon as the dish is put in an entirely dark room; it is considerably enfeebled if the sun's rays pass previously through a glass plate. A decided collapse of the leaves of the electroscope takes place when the dish is merely exposed to the blue light of the sky. If the dish is filled with hot or cold water the action is completely extinguished; a moist cloth stretched over it acts in like manner. By being illuminated the finely polished plate acquired a spontaneous charge of +2·5 volts, which by blowing on the plate could be still further increased.

The experiments are much simpler when the metals to be illumined are directly fixed in the form of wire to the knob of an Exner's electroscope. If freshly-polished wires are used—aluminium, magnesium, or zinc—a permanent negative electrification in the sunlight in the open is not at all possible. It is completely discharged in less than five seconds. Magnesium and aluminium wires act here more energetically than zinc ones. There is a perceptible collapse of the leaves when the former are used, even with the action of diffused evening light. It is also interesting to note that freshly-polished wires of the metals in question act as if an ignited body were attached to the electroscope. If an electroscope so arranged is taken to an open field, the leaves diverge with the use of freshly-polished wires with positive electricity, arising from the influence of the electricity of the air. In all these cases an abnormal diffusion of positive electricity could not be observe d. The experiments were made from the middle of May to the midd le of June in this year (1889).—Wiedemann's *Annalen*, Vol. XXXVIII., p. 40 (1889).

Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. *Telegrams:* "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
For Foreign Parts and Colonies:—	s. d.	s. d.	s. d.
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition, which is now on sale, consists of more than 600 pages of printed matter. Every care is taken to make the names and addresses of all persons engaged in the Electrical Industries absolutely accurate. Useful Tables and Electrical Formulæ are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

"The Electrician" will be Published, as usual, on Friday Morning in Christmas week, but Contributors and Advertisers will greatly oblige by forwarding their communications not later than Tuesday's post, as the Editorial, Printing, and Publishing Offices will be CLOSED on WEDNESDAY and THURSDAY, December 25 and 26.

LOCAL AUTHORITIES AND THE ELECTRIC LIGHT.

On several occasions recently we have commented somewhat fully on the singular rapidity with which the country has been overspread by electric lighting Provisional Orders; but in every case our remarks were confessedly subject to modification by fuller information not then at our disposal. This was especially the case in respect to the attitude of local authorities towards outside companies desirous of applying for powers within the municipal boundaries. We endeavoured to be fair to both parties, offering all the excuse we could think of for hostility on the one side, and deprecating any undue pertinacity on the other. Where local bodies were genuinely anxious to take up the matter on their own account, it seemed to us that for private undertakers to push themselves forward in opposition would result only in failure, and tend rather to cast discredit on the Electric Lighting Acts generally. The powers and dignities of local authorities have been greatly enhanced of late, and to provoke their united opposition would be not only futile, but highly impolitic, seeing that most of the electric lighting companies, if not permitted to undertake the installations, might do business by supplying the requisite plant. The action of some of the corporate bodies might not be altogether

Digitized by Google

disinterested or straightforward; but this, perhaps, could be said also of some of the companies, and as the Board of Trade can enforce a more effectual control over the former than over the latter, our advice was to let things take their course.

The fuller information to which we have alluded has reached us a little sooner than was expected. From several well-informed quarters protests have come to hand indicating a widespread suspicion that the local authorities, in many instances, are making common cause against the applicant companies merely for the purpose of keeping the electric light out of the towns altogether. This is said to be the case in places even where the gas lighting is in private hands, the idea being to prevent the inroad of a second monopoly, but with no serious idea of undertaking the new lighting business on their own account. If only time enough can be gained, it is thought that the private undertakers will disappear from the field, and that then the municipal applications can be quietly dropped. The worst offenders, however, seem to be those authorities who have acquired the local gas works, and whose "gas committees" are displaying a notable activity is seeking Provisional Orders, or private Acts of Parliament, to establish electric lighting works as well. On the face of it, such sudden desertion of the old love does not augur well for the new; and it is not surprising that disappointed electrical engineers are roundly charging the local lighting committees with a dishonest flirtation got up for the purpose of leaving the object of it forlorn and deserted.

But we have more solid grounds to go upon than the mere insinuations of rejected suitors. For our present purpose it will be sufficient to single out one conspicuous example of the kind referred to as confirmatory of the suspicions which have been openly expressed to us in respect to several others. At Glasgow, for instance, only the other day, the Town Clerk reported to a thinly-attended meeting of the Town Council, that the Gas Committee had decided to lodge with its memorial for an electric lighting Provisional Order a statement that a sum not exceeding £250,000 was proposed to be expended on the scheme. Although barely a quorum of members was present, this quarter of a million was sanctioned after a few minutes' desultory conversation, the whole tenor of which seemed to us as unreal as the proposal itself. It is only about two years since the Glasgow Corporation obtained £160,000 to extend the local gas works, and most of this money is spent. To suppose that they now intend to spend another £250,000, or anything like that sum, on electric lighting, is to credit them either with folly in the past or recklessness as to the future; and we find it hard to believe in either where Scotchmen are concerned. A similar observation applies to Edinburgh, where the acquisition of the gasworks dates only from last year; yet this is one of the places mentioned at the Glasgow meeting as acting conjointly with that city and with Aberdeen and Dundee in order to be properly represented in their procedure before Parliament next Session. There is reason to believe, as we have already hinted, that the combination here foreshadowed is not confined to Scotland, and that it extends, or will shortly be made to extend, to some of the more important gas-manufacturing Corporations south of the Tweed.

Now it would be idle to underrate the gravity of this combination, if it really exists for the purposes suspected; and that our apprehensions have a solid foundation is borne out by the fact of none of these corporate bodies making the least move towards obtaining electric lighting powers until applications were put forward by outsiders. We commend these considerations to the attention of the Committee of the Electrical Section of the London Chamber of Commerce, whose sources of information may be more ample than our own, and who, if our conjectures are found to be true, will no doubt take steps to protect the interests they have been elected to represent. It will not be difficult for the Committee to devise means to test the sincerity of the combination above referred to, by setting up a genuine case before the Board of Trade for admission to the sacred ground of one or more of these Corporations, and to show good cause for outside competition. Of course the Board will lean to the side of the local authorities; and we think rightly so, for they have a trust to discharge to their constituents which ought not be lightly set aside. But, on the other hand, the Electric Lighting Acts impose duties; and the Board of Trade have no choice but to see that the inhabitants are not debarred the use of electricity where they may desire it by any factitious opposition on the part of the local gas committees. In the end, probably the constituents will have to decide the matter by their votes; and to this there can be no objection whatever. What we do decidedly object to is to its being prejudged and settled by a small conclave who are more or less personally interested in maintaining the integrity of the Corporation gas works. Electricians would be content to have but a footing in the disputed areas; and this we think they are entitled to under the Acts, unless good reason can be shown to the contrary. Probably the local authorities are reckoning too much on their dignity and too little on the expressed intention of the Board of Trade to require that the electric light shall be supplied to the public either by local authorities, or, failing them, by any properly equipped company who may desire to undertake the task. Our friends, therefore, may feel reassured as to the ultimate result; and their Christmas holiday, which this year ought to be especially cheerful, need not be spoilt by the obstructive tactics of local magnates.

ON THE HEATING OF CONDUCTORS BY ELECTRIC CURRENTS.*

BY A. E. KENNELLY.

(Continued from page 145.)

The Heating of Bare Copper Wires and Strips Suspended in Air Within Doors.

It has been shown by Prof. Forbes and others that for bare cylindrical wires suspended in air, the temperature elevation produced in them by a current will be directly proportional to the square of the current and inversely to the cube of the diameter, provided that the loss of energy per unit surface of wire per second, known as the emissivity, be itself directly proportional to the temperature elevation. This assumption, though frequently made, is recognised to be untrue, and consequently this law cannot apply rigorously to suspended bare wires, just as it has been shown to be only approximately true for empanelled wires. Experiment shows that the emissivity rises rapidly with the rise of temperature, being in some cases nearly twice as great per degree Centigrade at 100 degrees as it is at 20°C. of temperature elevation. Hitherto in calculating the limiting temperature of a bare wire suspended in air the emissivity has been generally taken from the data supplied by the careful experiments of Messrs. McFarlane and Nichols, who observed the rate of cooling of large metal spheres in special enclosures, conditions which are not fairly applicable to the cooling of wires, and which cannot, as Prof. Forbes himself pointed out, be strictly depended upon for that purpose. He suggested that the effect of convection was not proportional to the surface, while radiation was; and experiments have verified this belief. Thus the emissivity for a polished copper surface in the experiments of McFarlane and Nichols was about 0·000168 therm per degree Centigrade between 0°C. and 60°C. With this value Forbes and others have been led to greatly under-estimate the carrying capacity of bare suspended wires. In the table accompanying his Paper already mentioned the calculated currents to raise the temperature of bright copper wires

* Abstract of Report read before the Edison Convention at Niagara Falls, August, 1889.

Digitized by Google

of 0·040in. and 0·120in. diameter 49°C. are 6·5 and 33·5 amperes respectively, while experiment shows that about twice as much current is needed in each case. In fact, the emissivity per degree Centigrade has been found to vary from 0·00019 therm, with a thin, flat, bright, copper strip, to 0·001364 therm with a bright copper wire 0·0356in. (0·0904 centimetre) diameter, at about 50°C. temperature elevation, or, in the latter case, some eight times as great an emissivity as that quoted from the previous data. A hot wire suspended in air parts with its heat both by convection and radiation. These two processes are essentially distinct, and are governed by different laws, so that the complete treatment of the subject can only be attained by dealing with each separately and summing their effects. The experiments to be described have succeeded in determining up to temperature elevations of 100°C. the separate rates of convection and radiation, together with the conditions to which they are independently subject. It is true that to determine all these conditions accurately would demand much further investigation, but the results appear to be at least reliable as a good first approximation. Instead of dealing with the emissivity in therms, as has been customary, it will be more simple and direct to give all the results in watts.

Fig. 3 A B C represents the temperature elevation measured with different current strengths passing through uninsulated copper conductors suspended in air within doors. Five different conductors were tested, and of these four were copper wires of diameters from 0·0356in. (0·0904 cm.) to 0·1345in. (0·341 cm.). The fifth was a strip of bright brush copper, 1in. (2·54 cms.) wide and 0·0065in. (0·0165 cm.) thick. Curves I., II., III., IV., V., VI., and VII. are the traces of the observations made upon them. Their surfaces were all brightened with fine emery paper, except that of the strip, which needed no polishing. The wires were suspended about 8ft. (250 cms.) above the floor, between opposite walls of the laboratory, in the still air with the windows closed. These precautions were taken because it was found that a comparatively small disturbance of the air exercised a decided cooling influence on the wire. Thus a fan gently waved beneath and at right angles to one of these 25ft. lengths of wire under test produced a diminution in its resistance that was plainly discernible, and arrangements were therefore made to keep the air as free from disturbance as possible. For the same reason all the observations, though they reached their practical maxima much more quickly than had been the case with the panelled wires, were more variable and never remained quite steady. The reading had consequently to be repeated several times and means taken to obtain fair results.

The emissivity of the strip (in its upright position, to be later described) proved to be 0·24 watt per linear centimetre, at 50°C. temperature elevation, its surface per centimetre being 5·11 sq. cms., while the emissivity of the smallest wire was 0·08 watt per linear centimetre at the same temperature elevation, its surface per centimetre being 0·284 sq. cm. Both these measurements being referred to the unit surface instead of unit length, give, respectively, 0·047 and 0·28 watts per sq. cm., thus making the emissivity of the small wire about six times as great as that of the strip for the same temperature elevation. From this great discrepancy it appeared probable that the convection, instead of being proportional to the surface, like radiation, was equal in both cases, or nearly so; for if the convection had been proportional to the surface the mere difference in the form of the two conductors, whose surfaces were of similar appearance, could hardly account for so large a discrepancy. By assuming the convection to be equal for both wire and strip, a pair of simultaneous equations was supplied by each pair of corresponding elevation points in the observation curves, thus giving radiation and convection independently for each such pair. The results for the radiation obtained in this way are:

Radiation for both wire and strip.

At °C. Temperature elevation.	Watts per sq. cm.	At °C. Temperature elevation.	Watts per sq. cm.
10	·004765	60	·04103
20	·01057	70	·04995
30	·01720	80	·05927
40	·02466	90	·06796
50	·03312	100	·07790

A rate of increase considerably beyond arithmetical progression. The test of the accuracy of the assumption on which these figures are obtained must be the accordance of this series with the laws of radiation as they are independently known.

MM. Dulong and Petit have published in the seventh volume of the *Annales De Chimie et de Phyisque*, 1817, a veritable poem in physical investigation upon the laws of cooling bodies. In their experiments the radiation was found to vary with the temperature elevation in geometrical progression expressed by the equation:

$$h = c\,(1{\cdot}0077)^{\theta}\left\{(1{\cdot}007)^{t} - 1\right\};$$

here h is the quantity of heat lost by radiation from a hot body per square centimetre per second; c, a constant depending on the nature of the radiating surfaces; θ, the temperature of surrounding bodies, and t the temperature elevation of the hot body in degrees Centigrade.

Taking this formula as representing the best existing knowledge of the rate of radiation with temperature, the test of the above assumption is in the accordance of the above series of calculated radiations with a similar series obtained from Dulong and Petit's equation, making t successively 10, 20, 30, &c., up to 100. The numbers so arrived at are:

$1{\cdot}0077^{10} - 1 = {\cdot}0797$	$1{\cdot}0077^{50} - 1 = {\cdot}4675$	$1{\cdot}0077^{80} - 1 = {\cdot}8471$
$1{\cdot}0077^{20} - 1 = {\cdot}1658$	$1{\cdot}0077^{60} - 1 = {\cdot}5844$	$1{\cdot}0077^{90} - 1 = {\cdot}9944$
$1{\cdot}0077^{30} - 1 = {\cdot}2587$	$1{\cdot}0077^{70} - 1 = {\cdot}7108$	$1{\cdot}0077^{100} - 1 = 1{\cdot}1534$
$1{\cdot}0077^{40} - 1 = {\cdot}3591$		

To test the degree of accordance between the two series, the fourth element corresponding to 40°C. (that being probably the most favourably situated for accuracy in observation) may be multiplied by 0·06866 to make it coincide with the calculated radiation 0·02466, and all the terms of the latter series may be similarly multiplied by the same factor. We then obtain the results given in the following table:—

Temp. elevation.	Dulong and Petit's series.	Factor of comparison.	Dulong and Petit's series referred to 40°C. elevation.	Calculated series from wire and strip.	Discrepancy.
Deg.					
10	·0797	·06866	·05473	·04765	– ·0007
20	·1658	...	·01138	·01057	– ·0008
30	·2587	...	·01776	·01720	– ·0006
40	·3591	...	·02466	·02466	Standard.
50	·4675	...	·03210	·03212	+ ·00002 min.
60	·5844	...	·04013	·04103	+ ·0009
70	·7108	...	·04881	·04995	+ ·0011
80	·8471	...	·05817	·05927	+ ·0011
90	·9944	...	·06827	·06796	– ·0003
100	1·1534	...	·07919	·07790	– ·0013 max.

This agreement must be considered very satisfactory, and it is difficult to suppose it merely coincidental. It not only strengthens the reliance to be placed on Dulong and Petit's law, but it also amounts to a demonstration that the convection does not depend upon the surface, or that at least it can only do so in a very limited degree.

The radiation in watts per square centimetre from a surface of bright copper may therefore be accepted as $0{\cdot}0687\,(1{\cdot}0077^{t} - 1)$ under the condition of these experiments. But Dulong and Petit's law requires that this factor 0·0687 should itself be a function of the temperature of surrounding bodies, or, in other words, that the radiation loss from a hot wire for a given temperature elevation increases with the absolute temperature. It may therefore be assumed that

$$\cdot06866 = c\,(1{\cdot}0077)^{\theta};$$

and in these experiments θ, the temperature of the surrounding air, was about 26°C., so that

$$c = \frac{\cdot06866}{(1{\cdot}0077)^{26}} = \cdot05625.$$

Whence the complete expression for the radiation from a bright copper wire in watts per square centimetre is:

$$\cdot05625\,(1{\cdot}0077)^{\theta}\,[(1{\cdot}0077)^{t} - 1].$$

It is to be observed, however, that this factor $(1{\cdot}0077)^{\theta}$ is a deduction only, as yet not verified by experiment. It is difficult to decide this point in the summer season, but it is hoped to determine the question of its existence experimentally during the ensuing winter by observing whether the radiation does vary to such a degree for giving temperature elevations when the temperature of surrounding bodies is changed. Should this factor's existence be verified it would completely establish the application of Dulong and Petit's law. If, on the other hand, the variation is not to be detected, while it would certainly weaken the position, the general evidence, apart from Dulong and Petit's law, is sufficient to maintain the use of the term $[(1{\cdot}0077)^{t} - 1]$, while the factor 0·06866 would necessarily be regarded as independent of θ. With this reservation, the retention of the factor is probably justified, especially as for most practical purposes the question is not a vital one.

The following table gives the radiation in watts per square centimetre of bright copper for $\theta = 25$°C., and if the factor $(1{\cdot}0077)^{\theta}$ be found to have an experimental existence it will be a simple matter to amplify the table for various values of θ from zero to 30°C.

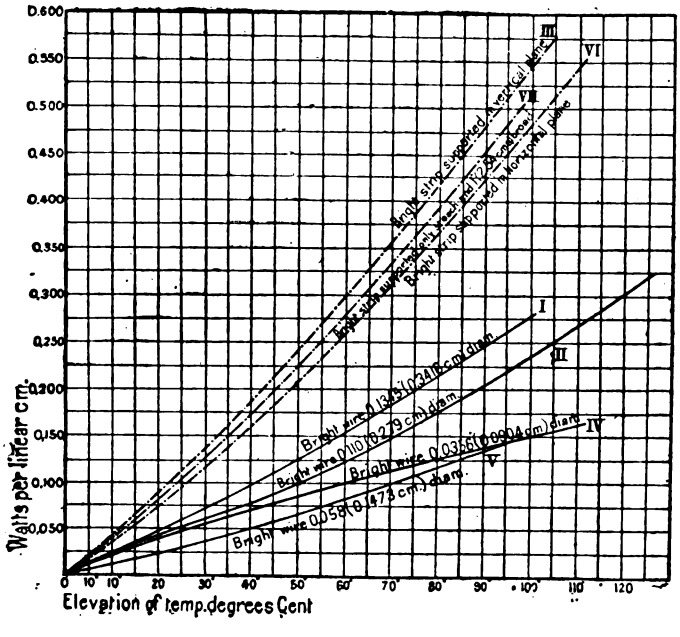
The radiation is thus roughly 0·0006 watt or 0·00014 therm per square centimetre per degree Centigrade, increasing in geometrical ratio; and one square metre of bright copper at 100°C. elevation would radiate about 800 watts.

The same series of simultaneous equations which gave the radiation values furnish also the convection for wire and strip and its rate of change. Figs. 3, A, B, C, gives the result of the analysis. Curves Nos. I., II., IV., and V., in Fig. 3A, represent the total emission in watts per linear centimetre as actually measured, and as composed of both radiation and convection. In Fig. 3C, the total radiation obtained in



Watts per linear cm.
Elevation of temp. degrees Cent.
Bright wire 0·0356 (0·094 cm) diam.
Bright wire 0·110 (0·279 cm) diam.
Bright wire 0·0356 (0·094 cm) diam.
Bright wire 0·056 (0·473 cm) diam.

FIG. 3 A.—Emissivity Curves.

the above manner is represented in the corresponding curves I., II., IV., and V., drawn to the same scale. The difference at each pair of corresponding points between the total emission and the total radiation represents the convection loss, and this is given by the lower set of curves, I., II., IV., and V., in Fig. 3B to the same scale. It will be observed that the convection was nearly the same in each case, the effect of increasing the diameter of the wire from 0·0356in. (0·094 centimetre) to 0·1345in. (0·3476 centimetre), that is, nearly four times, only appearing to increase the convection 20 per cent.; thus corroborating the results arrived at by the test of agreement with Dulong and Petit's law. The convection appears to increase rather more rapidly than the temperature elevation, except in the case of the smallest wire. This result is not in accordance with those of Dulong and Petit, who found the convection in their experiments with cooling spheres to increase as the power 1·233 of the temperature elevation, or according to the factor $t^{1\cdot233}$. It is quite possible, however, that the convection for spheres may not be the counterpart of that for long wires, and it is to be observed that not only are the laws of convection a branch of hydrodynamics more complex than those of radiation, which does not appear to vary with the form of surface, but the number and precision of these particular experiments scarcely warrant any more definite deductions to be made in this direction. For practical purposes therefore it will be sufficient to take a mean value of the convection and to assume it to be proportional to the temperature elevation until further investigation may afford more precise information. We may, therefore, take the loss of heat by convection from any wire at the mean value of 0·00175 watt per linear centimetre, in still air for each degree Centigrade of temperature elevation; that is, one kilowatt for every 114 metres at 50°C. temperature rise. Fig. 3A also shows that the total emission of a wire per centimetre may rise faster or slower than the temperature elevation, or may even trace a straight line proportional to the elevation for a certain distance, according to the dimensions of the wire and the relative proportions of convection and radiation in its

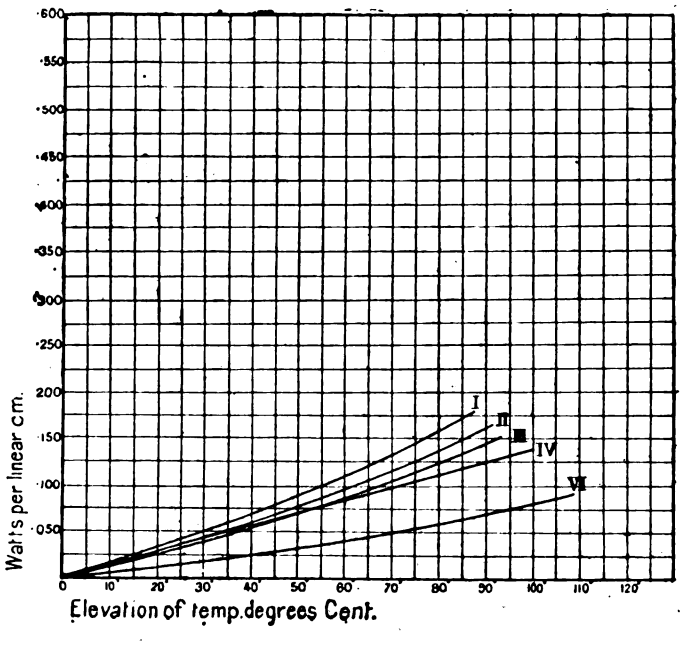


FIG. 3 B.—Convection Curves.

cooling. The smaller the wire the greater the likelihood appears to be of the rate of emission falling behind the rate of rise in temperature.

Experiments were next made to determine the amount of variation that a difference in quality of surface could effect in the rate of radiation. For this purpose five wires of the same dimensions and material—that is to say, five lengths of the same wire—were suspended parallel and their surfaces coated with different substances.

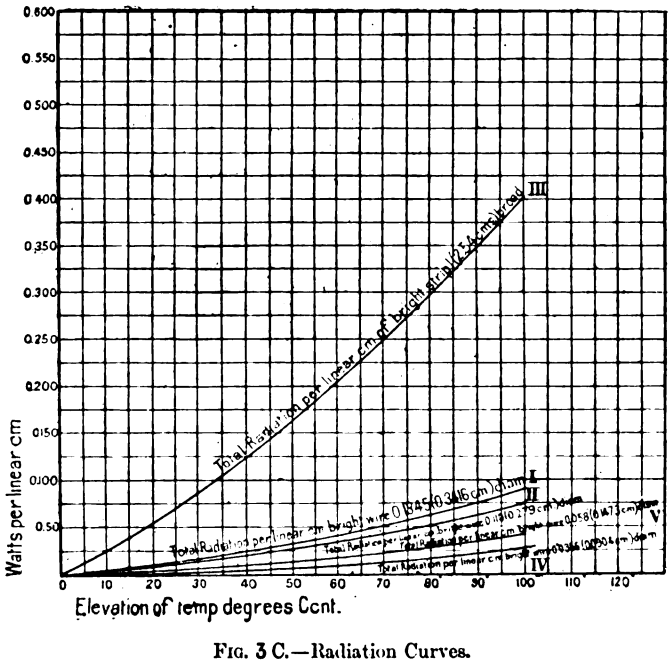

FIG. 3 C.—Radiation Curves.

On another occasion five lengths of the same strip were treated and experimented upon in a similar manner. The results showed that in still air a black coating of sulphide of copper, produced by painting the bright surface with a solution of sulphide of sodium, reduced the temperature elevation corresponding to any given current nearly 30 per cent. both for wires and strips; while a coating of lampblack and shellac (dead black carpenter's

Digitized by Google

varnish) similarly reduced the temperature of the strips nearly 50 per cent. This has a useful bearing upon bare copper conductors within doors, say in an illuminating central station, for if their surfaces are so large that the heat loss takes place principally by radiation (and for surfaces above 5 square centimetres per linear centimetre convection plays but a small part), the saving of energy produced by painting the conductors with this varnish will, through the lowered temperature and resistance, amount to $\frac{t}{6}$ per cent., where t is the previous temperature elevation. So that if these conductors be maintained at 50°C. elevation in the bright state this will fall to about 27°C. after painting, with a resultant saving of about 8 per cent. of the whole energy previously generated by the current in the painted length. This applies not only to bright copper, but also to copper that has become slightly tarnished by age, but may not apply equally to copper whose surface is encrusted with dust or smoke.

By first determining the radiation and convection for the bright wire and strip, then assuming the convection to be equal for the other coated wires and strips respectively, the mean ratio of the radiation from each quality of surface to the radiation of bright copper was calculated to be as follows :—

For the wires.—Thin coating of brown shellac varnish, 1·62 ; thick coating of copper sulphide (CuS), 2·34 ; thick coating of lampblack made adherent by molasses, 2·05.

For the strips.—Thick coating of brown shellac varnish, 1·84 ; rather imperfect and thin coating of copper sulphide, 1·54 ; lampblack by deposit from smoky candle, 1·42 ; thin coating of varnish, lampblack, and shellac, 2·02.

The coating of copper sulphide was not so successful in promoting radiation with the strips as with the wires, partly owing, however, to imperfect cooling. The necessity for a compact adherent layer in obtaining active radiation is also shown, for while lampblack, deposited from a flame, only added 42 per cent. to bright radiation, lampblack applied with thin shellac varnish doubled it. We may therefore take the radiation from a properly blackened wire as double that from a bright wire.

Experiments were also made with two strips of bright copper to ascertain how far their convection was affected by their plane of suspension. In the above-mentioned tests of strips they were all secured at their extremities to lie flat ; but toward their centre they each dipped to one side or the other out of the horizontal plane, making a dip of about 45deg., and the following tests were made to determine whether the convection depended to any extent upon this angle : These two strips were supported in air at about every 3ft., one of them being fixed in the vertical plane, while the other rested flat above all the supports. Their perpendicular distance apart was 8in. (21 centimetres). The testing current was sent through them in series and the temperature elevations determined for each in the usual way. Curves III. and VI., Fig. 3A, represent their relative behaviour. In the first trial the temperature elevation of the flat strip reached 120°C., at 101 amperes, while that of the upright was only 102·5°C. To make certain that this difference was not due to any inequality of radiating power, the strips were exchanged in position, the upright one being now flat, and *vice versâ*. On repeating the test, the temperature elevation of the flat strip reached 120·5°C. at 100 amperes, while that of the upright strip was 101·3°C., practically the same result, and the only means of accounting for the difference was the plane of the strips. The diagram shows that the emission of the upright strip was greater than that obtained from it in the previous test while unsupported and drooping, and the emission from the flat strip less—a result quite in accordance with expectation. Fig. 3B gives the calculated values of the convection from the upright and flat strip. The latter is seen to be about 45 per cent. less than the former, a rather surprising difference, for it would indicate that, supposing the upper surface of the flat strip to be equally affected by convection to the same degree as one side of the upright strip, the convection from the lower surface would then be ten times less.

The final results of the experiments on bare wires in still air point to the following means of calculating the current strength necessary to raise any given copper wire to a certain temperature elevation :—

Let d be its diameter in centimetres ;
t ,, the given temperature elevation ;
r ,, its resistivity at 0°C., in ohms ;
θ ,, the temperature of surrounding objects ;
m ,, the coefficient of surface for radiation.

Let $t+\theta=T$, the temperature attained by the wire.

Then its resistance per centimetre will be—

$$\frac{4\,r\,(1+\cdot00388\,T)}{\pi\,d^2}\text{ ohms.}$$

The energy developed per centimetre by a current of c amperes will be—

$$\frac{4\,c^2\,r\,(1+0\cdot00388\,T)}{\pi\,d^2}\text{ watts per centimetre.}$$

The heat convected from it will be : $\cdot00175\ t$ watts per centimetre.

The heat radiated from it will be :

$$d\,m\,\pi\times\cdot0687\,[(1\cdot0077)^t-1]\text{ watts per centimetre.}$$

Or if the radiation for t deg. elevation be taken from the previous table and denoted by R^t :

The total radiation per linear centimetre $=d\,m\,\pi\,R_t$ watts. Equating the gain and losses,

$$\frac{4\,c^2\,r\,(1+\cdot0388\,T)}{\pi\,d^2}=\cdot00175\,t+d\,m\,\pi\,R_t\ ;$$

whence,

$$c=\cdot886\,d\sqrt{\frac{d\,m\,\pi\,R_t+\cdot00175\,t}{r\,(1+\cdot00388\,T)}}\ ;$$

for copper of 98 per cent. conductivity $r=1\cdot65\times10^{-6}$; so that simplifying—

For bright wires :

$$m=1,\ c=28\cdot9\,d\sqrt{\frac{570\,Q\,R_t+t}{1+\cdot00388\,T}}\ ;$$

for blackened wires :

$$m=2,\ c=28\cdot9\,d\sqrt{\frac{1140\,Q\,R_t+t}{1+\cdot00388\,T}}\ ;$$

where $Q=\pi\,d$, the circumference of the wire.

The following table of current strengths capable of elevating the temperature of bare copper wires of 98 per cent. conductivity suspended in still air, 5 degrees, 10 degrees, 20 degrees, 40 degrees, and 80 degrees above surrounding air and objects at 20°C., has been calculated for bright and blackened wires by the use of these formulæ It will be observed that the currents are given up to 1,500 amperes,

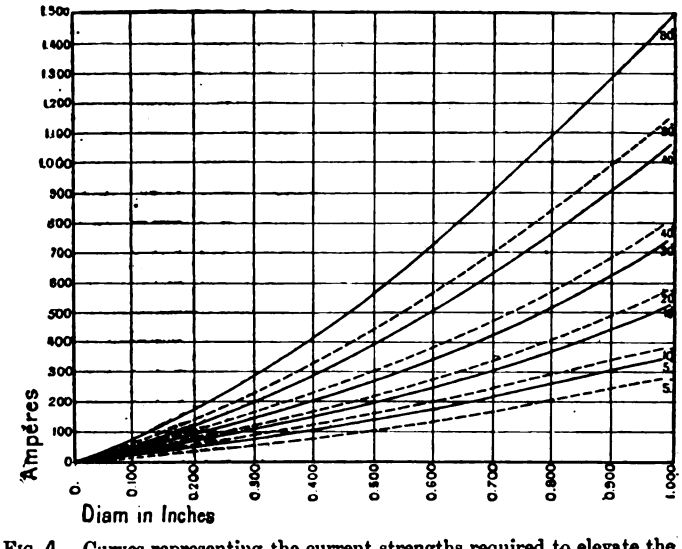

Fig. 4.—Curves representing the current strengths required to elevate the temperature of wires of diameters up to 1in., 5, 10, 20, 40, and 80°C. ; for bright and blackened copper of 98 per cent. conductivity in still air at 20°C. Broken lines refer to bright copper; full lines refer to blackened copper.

while 100 amperes was the experimental limit to which this series was carried. To present, however, a comparison of the results calculated in the table with those actually measured up to that limit, the following may be noticed :—

(To be continued.)

THE ELECTRIC LIGHT IN ENGLISH TOWNS.

The following extracts from Appendix A of the elaborate report recently presented to the Dublin Town Council by the Electric Lighting Committee may prove of interest :—

Liverpool.—The Liverpool Electric Supply Company have had a licence from the Board of Trade since the early portion of last year, and this year have got a Provisional Order with the consent of the Corporation. In this Provisional Order (which is for certain portions of the City only) the Corporation have had inserted the requisite clauses for their protection as

Digitized by Google

regards the mode of laying the mains and taking up and reinstating the pavements disturbed, and charge the company the actual cost, with an addition of 10 per cent. The bills for these street openings are made out and paid weekly, and the Corporation, under the provisions of the order, hold in reserve £500 of the company's money. This sum has always to be maintained as a deposit for the protection of the Corporation.

The company charge for the electric light the following, viz. :—For the first 100 hours (per quarter) at the rate of 1s. per Board of Trade unit; between 100 and 200 hours at the rate of 8d. per Board of Trade unit; any number of hours over 200 at the rate of 4d. per Board of Trade unit. The underground wires for electric lighting are now being laid in the thoroughfares of the city. The method adopted is to place the tube containing the wires in a cast-iron casing, with sockets (somewhat resembling a square rain-water pipe cut in two parts longitudinally); this trough being then filled with bitumen, and finally covered on top with cement, forms the complete arrangement for protecting the cables. The new electric mains and cables have not been yet brought into requisition, and up to the present time there is no public electric lighting in Liverpool. The system will be all high tension, reduced in the ordinary way by transformers. Siemens' dynamos and Willans' steam-engines are used in the several stations in the city. The average annual period of public lighting by gas is 4,000 hours, and the price is from 2s. 9d. to 3s. per 1,000 cubic feet.

Bradford.—The gas works in Bradford are the property of the Corporation. The Corporation, under a Provisional Order, is about to distribute the electric current for domestic lighting, motive power, and other purposes. It is not intended to introduce public electric lighting under the scheme until it is ascertained to what extent the public will avail themselves of the electric supply, and also in consequence of the great success of the gas undertaking. The new light is at present intended for the illumination of houses and buildings in the central portions of the town. The necessary works are estimated to cost £24,000. The Corporation proposes to supply the light at a charge of 5d. per Board of Trade unit. In regard to machinery and plant, the central station contains three Siemens dynamos, each of 600 amperes and 150 volts; two engines by Willans and Robinson, and one by Marshall, Sons, and Co., each of 150 horse-power indicated; three steel boilers by Holdsworth and Sons, of Bradford (Lancashire type). The engine room is 60ft. by 21ft. Eight and a-half miles of electric mains have been laid, the wires being encased in lead pipe, with an outer covering of tarred jute. The cables are simply laid in the ground, generally under the pavement, save in certain places across passages and roads, where small brick culverts are constructed as an additional means of protection for the mains from the heavy traffic.

Leeds.—The Corporation of Leeds own the gas works, and they supply gas to the public at the price of 1s. 10d. per 1,000ft. The Corporation of Leeds have been engaged in carrying out experimental works in electric lighting since May, 1883 (see *Electrician*).

Sheffield.—The Sheffield Telephone Exchange and Electric Light Company (Limited), with a capital of £60,000, has installed the only system of electric lighting in Sheffield, but without any special powers or authority to light the town. The Corporation did not oppose the company, or promote any scheme of electric lighting on its own behalf. The Thomson-Houston system is used for arc lights at high tension. There are three dynamos for producing a total of 150 arc lights, each of 2,000 candle-power, and each dynamo works up to 2,000 volts. These machines were made in America, and each of them requires 40 horse-power in the working. There is also a 700-light Mordey alternator, made by the Brush Electric Light Corporation. Orders have been received for all the lights that the present machinery can produce, and more appliances will be laid down forthwith. The engine is by Tasker, Sons, and Co., and has a Galloway boiler in connection with it. The charges are :—For one arc lamp £20 per annum (equal to a penny and a fraction per hour); two ditto, £35; three ditto, £50. Incandescent lamps, 23s. for each lamp of 16 candle-power, and the transformers for incandescent lighting are fixed on the consumer's premises. The works produce 150 arc lights of 2,000 candle-power nominal, with actual light of 1,000 candles through the opal globes. Incandescent lighting only admits of comparison with gas in regard to cost. The company in Sheffield asserts that it can manufacture and supply electric light with profits equal to what would be gained from gas at 4s. per 1,000ft. The company's undertaking in Sheffield yields a dividend of 7½ per cent. and, in addition, a large reserve fund has been created; but the company carries on a large telephone exchange business in addition to the electric light. The charges for gas in Sheffield are regulated according to scale—viz., 2s. 4d. per 1,000ft. to ordinary consumers, but for large supplies up to 500,000ft. 2s. 2d. per 1,000ft. is charged, and 2s. between 500,000ft. and 6,000,000ft., and 1s. 10d. per 1,000 cubic feet for any greater quantity. The price paid for public lighting by gas is 1s. 10d. per 1,000 cubic feet.

Eastbourne.—The electric light was introduced in September, 1882, by a local company, with a share capital paid up of £12,500, recently increased by some £5,000 Debenture Stock. The company began operations on the series system of lighting, but found it advisable to alter the works to the alternating or parallel transformer system instead. As a result, it is hoped that the company will be in a position to realise a profit, notwithstanding the increased price of coal from 19s. to 25s. 6d. per ton. The water for steam power costs the company 1s. per 1,000 gallons. The wires conveying the currents are all underground, and the public lighting system is entirely separate and apart from the private supply. In all there are 2,300 incandescent and 21 arc lights, for which the following charges are made :—Incandescent lights: 1s. per unit for first 100 hours in quarter; 8d. for second hundred hours; 4d. for any greater number. Arc lights—The Corporation pay the company £30 per annum for each arc light.

The company uses one compound engine (Fowler) of 200 horse-power, and two dynamos (Lowrie-Parker) with an output of 50 and 70 units respectively. This is sufficient to supply 2,000 16-candle-power lamps at one time. The steam for the engine is supplied from a tubular boiler of the locomotive type working at 140lb. pressure per square inch. The cables are $\frac{7}{16}$ths and are laid underground in 3in. gaspipes. The wires are enclosed in three layers of india-rubber, with an outer covering of stout braiding. The present price of Welsh coal in Eastbourne is 25s. 6d. per ton. Gas supplied to private consumers costs 3s. 7d. per 1,000 feet, and the charge for public lighting is at a somewhat lower rate.

Hastings.—Electric light has been installed by a company with a nominal capital of £50,000, of which about £14,000 is issued. The cost of production and supply is slightly in excess of gas, and the company, which pays a dividend of 3 per cent. on the undertaking, is now negotiating to transfer the work to the local authority.

The company supplies 1,000 incandescent lights to hotels and other places, of from 8 to 10 candle power each, and 30 Brush arc lights, each of 2,000 candles nominal. For the latter the company is paid £30 each per annum. There are 20 miles of underground wire in Hastings, the cables being $\frac{7}{16}$ strand, cased in gutta percha, with other material for outer covering. The factory and workshops, built at a cost of £4,000, are of three stories, the upper story being set apart for workmen's dwellings. The machinery includes five Brush dynamos; two 40 horse-power Robey boilers and engines, one of which is sufficient for the work, and one large multitubular steel boiler of 100 horse-power, by Duncan, Stewart, and Co., Glasgow.

The scale of charges for electric light in Hastings is as follows :—Cost of installation (not including brackets), one group of eight lamps. £5; each succeeding group, £4; supplying light from sunset to 11 p.m., £2 per lamp per annum; supplying light from sunset to 8 p.m., £1. 10s per lamp per annum. If supplied by company's meter, ½d. per lamp per hour: Installation for one arc lamp, £5; lighting for one arc lamp, £30 per annum. The company will lay mains to consumers' premises. Coal is brought to Hastings by rail from Yorkshire *vid* London, and costs 18s. 10d. per ton, with the addition of 2s. 6d. for town dues, making in all 21s. 4d. per ton. The charge for gas is 3s. 4d. per 1,000ft. The County Council of Hastings are under a contract with the company as to lighting the front line at £30 per light per annum for each arc lamp.

Rochester.—In Rochester electric lighting is carried on very successfully by a local company, which is working at the present time without statutory powers; but the necessary steps are now being taken to obtain a Provisional Order. The system employed is that of high-tension alternating currents, in conjunction with transformers.

The plant now at work is at present supplying what is equivalent to about 3,000 lamps of 10 candle-power each, but it is sufficient for 4,000 lamps of like power, and has cost £13,000, which includes three items of extraordinary expenditure, as follows :—1. £1,300 for sinking and boring an artesian well 339ft. deep, which affords a constant supply of water at the rate of 30,000 gallons per hour. The water is used for condensing and other purposes; great economy in working being thereby effected, as there is a saving in fuel to the extent of nearly 50 per cent. 2. £1,000 for engine and dynamo foundations, which had to be made in a very substantial manner. The station is erected in a very convenient situation on a wharf, on the River Medway, where coal, &c., are readily landed, but where the sub-soil to a depth of 50ft. consists of nothing but river mud, through which wooden piles had to be driven into the solid chalk below to support a solid block of concrete 18ft. in thickness. 3. £2,000 for lamps, wires, and other miscellaneous stores required for installing the light in public and private buildings, clubs, shops, dwelling-houses, &c., the company doing the whole of the fitting work themselves. The mains are carried overhead on poles, there being two circuits, each about two miles in length. At the present time the company have no portion of their plant in duplicate. The dynamo was supplied by Mr. S. Z. de Ferranti, of London, and is of the 1888 type: 150 estimated horse-power, and cost £1,050. The engine employed is of the horizontal type, surface condensing, 4ft. stroke; it is fitted with Corliss valve gear, and Knowle's patent supplementary governors. The driving-wheel is 20ft. in diameter, cotton ropes being employed for gearing. The engines were made and supplied by Messrs. Hick, Hargreaves, and Co., of Bolton. The Babcock and Wilcox Company, of London and Glasgow, supplied the boiler, which is of their well-known water tube pattern. Later on it is intended to employ the foregoing plant for day work only. Steps are already being taken for laying down plant four times the size of that already installed. The uniform charge for current supplied is 6d. per Board of Trade unit. The anticipated income for this year from the lamps at the present time supplied is £2,500, which is calculated to yield 11 per cent. dividend on the invested capital, after a liberal allowance for depreciation on plant has been made. It should, however, be borne in mind that working expenses are kept very low, one man alone, for example, attending to boiler, engine, and dynamo. The charge for gas at Rochester is 2s. 3d. per 1,000 cubic feet.

West Brompton.—This central electric lighting station, adjoining the West Brompton station of the Metropolitan District Railway, was opened on January 24, 1889, by the House-to-House Electric Light Supply Company (Limited), which has expended about £35,000 on plant and works, and expects to realise a substantial profit from the undertaking. The buildings are most admirably designed, and are constructed with a view of extension in the future. The plant installed is on the Lowrie-Hall system, and is divided into three units. Each unit consists of 150 estimated horse-power, each capable of producing electricity for 4,000 lights, and in order to always have a margin of power in case of break-down, the maximum work done by the station will be the supply of electricity for 8,000 incandescent lamps. In case, therefore, of any one unit having to stop when the full load is on, the remaining two will be able to easily carry on the work. In connection with this plant 12,000 lamps may freely be let out,

Digitized by Google

wiring in the houses on the circuit being done for this quantity, as in practice it is found that never more than two-thirds of the total number of lamps wired for are in use at one time.

While in London your committee inspected the works of Mr. Sebastian Ziani de Ferranti, at Charterhouse-square. Here the manufacture of all descriptions of electrical appliances—many the inventions of Mr. Ferranti—is in operation on an extensive scale. One dynamo working up to 2,400 volts, driven by an engine of 150 horse-power, was taken asunder, portion of the armature removed, replaced, and the machinery again put in motion in a few minutes. This rapid taking apart of the machine and the ease with which coils can be replaced are rightly considered by the inventor to be two of its most valuable features. A dynamo sufficient for 200 lights can be supplied for £85, but as the smallest size machine Mr. Ferranti stocks is for 3,000 lights, machines for a less number of lights would have to be specially made to order.

CORRESPONDENCE.

THE BEHAVIOUR OF FLAMES IN THE NEIGHBOURHOOD OF INFLUENCE MACHINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Shelford-Bidwell, at the Physical Society, and yourself, in your editorial column, have made reference to the behaviour of flames in the neighbourhood of the electrostatic induction machine. Will you, therefore, permit me, on behalf of Sir Archibald Campbell, of Blythswood, and myself, to describe very briefly some observations which we made last March, but which we did not intend to publish until we were able to give results of further investigation of the subject.

I may say that Sir Archibald Campbell has constructed, at his laboratory at Blythswood, two Wimshurst machines of very great capacity. The second, indeed, is not complete: it is being built in sections, and when finished will give an enormous quantity of high potential electricity. Already a *current* of one or two milliamperes, at a potential of some thousands or hundreds of thousands of volts, can be obtained; and we have measured the current, under definite conditions, by electrolysis of acidulated water in capillary tubes, making use of a device of the late Prof. Andrews for the purpose.

When a common candle is brought near to one or other of the conductors of the machine, the flame is of course blown about by the air currents, which can be felt rushing off from any points of dust that may be sticking to the polished surface of the conductor. If the discharging rods are tipped with clean polished balls of, say, 2in. diameter, and a lighted wax vesta is held a little below the horizontal line joining the centre of the balls, the flame is pulled out on both sides, so as to look like an ordinary bat's-wing gas jet. If a lighted candle is brought near to the positive globe it is extinguished, the flame being driven about in a very curious way, which I will not attempt to describe just now. If, however, the flame is brought near to the negative globe it is not blown out; but, on the contrary, if the wick has a bright smoking spark at the top, the flame is *relighted* by the sparks which play down the smoke column on to the wick. The relighting cannot be done at the positive globe by any torrent of sparks, so far as we have seen.

A lighted spirit-lamp put on the positive conductor is extinguished almost as soon as the handle of the machine is turned. But if put on the negative conductor it is not easily extinguished. If, however, the machine is turned very rapidly the flame is blown out. This observation was made by Messrs. M. Maclean and Makita Goto in the course of experiments on electrification of the atmosphere by flame. The phenomenon seems to be a mixed one. The blowing out of the flame on the negative conductor when the machine is in very vigorous action depends, no doubt to some extent, on the air currents generated.

—Yours, &c., J. T. BOTTOMLEY.

December 14, 1889.

ELECTRIFYING STEAM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: There seems to have been a little misunderstanding at the Physical Society last Saturday, judging from your report on Mr. Bidwell's Paper and its discussion.

Prof. Silvanus Thompson, who was kind enough to mention my work as bearing on the subject, is said to have suggested that Mr. Bidwell's observation of the increase in size of the globules was contrary to what had been noticed and described by Mr. Clark and myself (see *Nature*, July 26, 1883, xxviii., p. 297; *Phil. Mag.*, March, 1884; and *Proc.* Roy. Inst., May 28, 1886); but the fact is that it is essentially identical.

Electrifying a fog, whether a steam fog or any other fog, causes the small particles to coalesce into larger ones, and consequently to fall as rain or coarse mist.—Yours, &c.,

December 13, 1889. OLIVER J. LODGE.

[We rather understood Prof. Thompson's remarks to be directed to the contrast in time between the two phenomena: the instantaneous increase in the opacity of the steam jet, being contrasted with the comparatively slow clearing of the fog in Prof. Lodge's well-known experiment.—ED. *E.*]

DISC WINDING.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the conclusion of Mr. A. T. Snell's article, "A Comparison between the Continental, American, and English Dynamo-Electric Machinery," which you published last week, there is a diagram (Fig. 26, p. 140) which is given as illustrating the "New Edison Disc Winding," and is referred to in the text as having been patented in 1887. I wish to point out that the method of disc winding illustrated in the diagram referred to, is described in my patent, No. 717, dated January 17, 1887, Disc-Dynamo-Electric Machines and Motors.—Yours, &c.,

W. B. SAYERS.

24, Glycena-road, Lavender-hill, London, S.W.,
December 17, 1889.

THE ELECTRIC LIGHT AT TEMESVAR.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We notice in your issue of the 6th inst. a communication from your Vienna correspondent, in which a case of fire due to electricity is reported from Temesvar. As the information is evidently taken from the grossly exaggerated reports which found their way into some of the daily papers, we ask to be allowed to correct these statements.

Owing to a piece of lead-covered cable fixed against a brick wall in a court-yard being injured, a short circuit lasting only some few seconds occurred. There was no casing to catch fire, the fire brigade did not extinguish the flames, nor was the town in any degree alarmed. In proof of this we may mention that the general public knew nothing of the matter, and every one was astonished at the reports published in the Vienna papers —sent in, no doubt, by some reporter in want of sensational matter.

Asking you to kindly find space for the above, we remain,

Yours, &c., F. W. CLEMENTS,
General Representative for Hungary of the Brush Electrical Engineering Company.

Temesvar, Coronini-Platz, December 11, 1889.

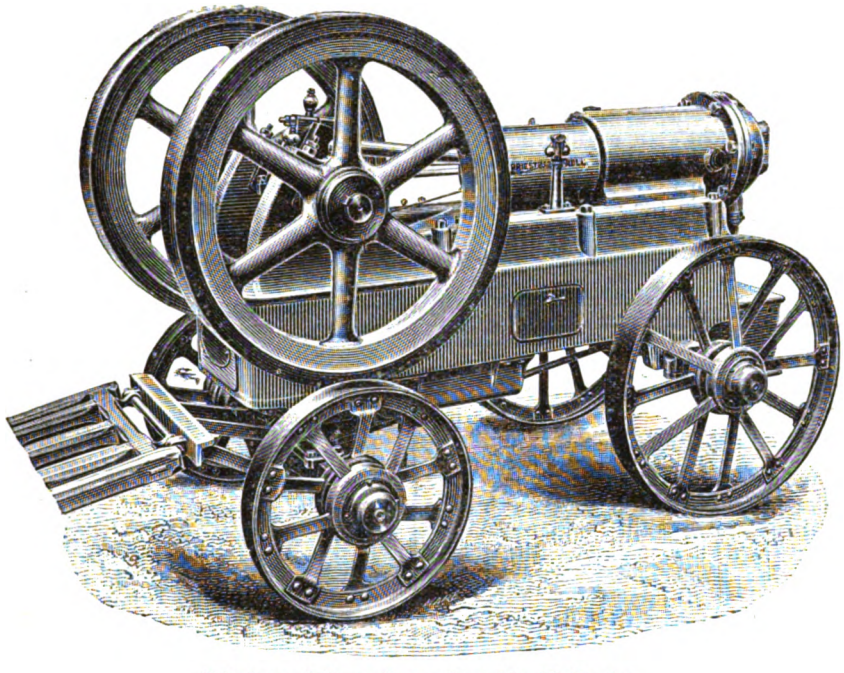
THE PRIESTMAN OIL ENGINE.

Since its first introduction, some few years ago, the Priestman engine has been considerable improved, and, as a consequence, it is now steadily making its way. The uses to which a reliable portable engine, requiring little attention and few repairs can be put, are so numerous that it is not surprising to find an engine like the Priestman which fulfils these requirements to so large a degree, should be in great demand For driving dynamos in connection with installations in country houses, a good oil engine is especially useful.

One special feature of this engine is that it uses the common petroleum oil of commerce and not petroleum spirit, which has a very low flashing point. The general arrangement of the engine is similar to a gas engine, the cycle being the same as that of the "Otto." The power is obtained by forcing the oil, which is contained in a small tank, by means of air pressure into a vaporiser, where it becomes mixed with the requisite quantity of air to form a combustible charge, which, being heated, passes into the cylinder,

Digitized by Google

Here it is at first compressed and then fired by an electric spark. The exhaust passes away round the vaporiser and forms the heating power for the incoming charge, and thence passes into the open air through an exhaust pipe. The engine requires little or no attention after starting, and can be safely left to run on by itself. The cost of working is small and no driver is required. By recent improvements in the engine, the oil consumed has been as low as 1·2 pints per actual horse-power per hour, which at the present cost of oil is less than 1d. per actual horse-power per hour. No lubricating material is required for the cylinder, as the charge itself does all that is necessary in this way. The most general form of the engine is the ordinary horizontal type, two forms of which are supplied—one being the engine itself mounted upon a substantial pole plate and having a separate tank for circulating water, the other form consisting of the engine mounted upon a substantial cast-iron tank or water vessel, which in itself forms a massive foundation. In addition to the horizontal types, a portable engine (*see* Figure) has lately been introduced, and at the present time the construction of both launch and tramcar engines is under consideration. Many minor improvements have lately been made in the construction and working of these engines, more particularly so as to ensure economical and reliable working, and to still further simplify the attention necessary. A new form of electrical battery has been added, which is an ordinary storage cell which will last for from two to three months working daily, and is easily re-charged.



Triestman 6 Horse-Power Portable Oil Engine.

As an additional proof of the value of this engine we have only to add that it secured the silver medal of the Royal Agricultural Society at Nottingham last year.

LEGAL INTELLIGENCE.

United Telephone Company v. Tasker.

Mr. RENSHAW, Q.C., moved, before Mr. Justice Kay, on Friday last, to dismiss the action of the United Telephone Company *v.* Tasker for want of prosecution, on the ground that the plaintiffs had failed to comply with an order for a further and better answer to the interrogatories administered by the defendants. He said the action was brought to restrain an alleged infringement of the Bell Telephone Patent, and the defendants put in a defence and counterclaim for damages, on the ground that the plaintiffs, having made an agreement with the defendants as to supplying them with telephones for the purpose of a telephone exchange at Sheffield, afterwards promoted by a rival company, the National Telephone Company, the setting up of a rival exchange in the same town. In connection with this matter interrogatories were administered, the answers to which had been decided to be insufficient, and on November 20th an order was made that the plaintiffs put in a further and better answer within 14 days. A further affidavit was filed on December 4th, but this, he contended, was also insufficient, and he, therefore, brought the present motion ; the real object of which, of course, was not to have the action dismissed, but to have a full and sufficient answer.

Mr. BOUSFIELD having also pointed out the insufficiency of the answer, and urged that the defendants were entitled to bring this motion under Order 21,

Mr. MICKLEHAM, for the plaintiffs, contended that the answer was sufficient.

Mr. JUSTICE KAY decided that the answer was not sufficient ; at the same time he exceedingly disapproved of the method which had been adopted for bringing the question before the court by way of motion, instead of taking out another summons for a better answer. He should, therefore, order a further and better answer within a week, but should not give the applicants their costs.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

Appointments Vacant.—The London County Council advertise for an inspector to test electric lines, certify meters, &c. The salary is £200 per annum ; an assistant-inspector is also required, at a salary of £2 per week. An inspector is also advertised for, whose duties will be to supervise the work of the electric light companies in the public thoroughfares, the salary being £3. 3s. per week. Applications are to be sent in by January 7th next. Full particulars are given on p. XIII. of advertisements.

——— The Metropolitan Asylums Board require an engine-driver to attend to the electric light installations on board the hospital ships lying in the Thames at Long Reach, near Dartford. Applications to be in by December 23rd. Further particulars will be found on p. XIII. of advertisements.

Admiralty Contract.—Messr. Humphrys, Tennant, and Co. have recently supplied new machinery for several vessels under construction, which includes engines, &c., for the electric light.

Tender Accepted.—The tender of Mr. F. A. Harper, of Balinasloe, has been accepted for putting up electric bells and batteries at the District Asylum, Balinasloe, Ireland.

Personal.—Mr. J. D. F. Andrews has, we are informed, withdrawn from the firm of Messrs. Muir, Mavor, and Coulson, of Glasgow, and has set up as a consulting electrical engineer, at Botolph House, Eastcheap.

Glass Globes for Electric Lighting.—We have received from Messrs. A. and R. Cochran their illustrated catalogue of new designs in glass globes and shades for electric lighting. Some of these designs are very artistic and elegant, and we would specially commend Nos. 3,080, 3,082, 3,088, 3,093, 3,127, 3,244, 3,261, 3,346 3,384, and 3,385.

——— We have also received from Mr. Carl Quitmann a sheet of designs of globes and shades. The sheet also includes diagrams of incandescent bulbs, bushes, insulators, &c.

Digitized by Google

THE ACME ELECTRIC WORKS.—This Company have recently taken offices at 17, Princes-street, Hanover-square, London, W., where a stock of their specialities will be kept. The works remain at Ferdinand-street, Chalk Farm-road, N.W.

THE PHONOGRAPH AND THE TYPEWRITER.—An interesting demonstration of the use to which the phonograph can be applied was given on Saturday last to a number of representatives of the press, at the offices of Messrs. J. and W. Richardson, 12, Queen Victoria-street, E.C. Messrs. Richardson are the proprietors of the Bar-lock typewriter, and it was in conjunction with this that the phonograph was used. The "typist" sat at his instrument, and on his left was placed a phonograph, worked by a small electric motor, a stout cord and treadle being used to stop or start the cylinder of the phonograph when necessary. A cylinder being put into position, the "typist" placed the pair of tubes to his ears, and proceeded to reproduce the messages or letters which had been previously spoken thereon. As the speed of the cylinder can be easily regulated, or stopped, or put back, the operator experienced no difficulty in following the message, the result being that a faithful copy of the record on the cylinder was taken. It is unnecessary to point out to business men the far-reaching possibilities of such a combination. The representatives present expressed their admiration at the improvements made in the phonograph, and not a little praise was bestowed upon the compact electric motor used. Colonel Gouraud is at present in America, but his representative was present, and informed us that, simple as it all was, he was instructed to say that the more perfect instrument which Mr. Edison has now completed, and which will shortly be introduced, will render the combination still more effective and popular. While upon the subject of typewriters, we may mention that recent improvements made in the Bar-lock Typewriter include an arrangement by which the reversing of the inked ribbon is automatically effected, and a pointer enables columns of figures to be easily written in exact alignment. In engineering offices this improvement will be fully appreciated. The type-written matter is also now in full view of the operator. A further advance has been made by Messrs. Richardson, in the discovery of an ink which will dry rapidly enough to admit of thousands of copies being taken off a typewriter letter and folded and enveloped at once.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

November 21, 1889.

18,604. J. PERRY, C. E. HOLLAND, and H. B. BOURNE. Hampstead. The measurement of and regulation by electric currents.

18,608. J. W. HARTLEY. Stoke-on-Trent. Compensator for signal wires.

18,638. A. DICKINSON. Birmingham. Improvements in the mode of driving electrical vehicles.

18,651. J. A. MCMULLEN. London. A system of conducting and distributing at a distance electric currents of large quantity from a low pressure continuous current generator.

18,654. R. H. GOULD and E. UBRIG. London. An automatic electrical device for signalling changes of temperature.

November 22, 1889.

18,700. T. W. WATSON and A. H. WATSON. London. Improvements in connection with electric battery cells.

18,712. J. B. VERITY and J. C. GIRDLESTONE. London. An improved form of connection for electric lamps for stage battens, footlights, &c.

18,740. F. KING. London. Improvements in couplings or clutches, more especially applicable to the driving of dynamo-electric machines connected in parallel.

18,743. S. PITT. London. Improvements in cables containing electric conductors (A. Day, United States).

18,755. A. RECKENZAUN. London. Improvements in the manufacture of plates for use in secondary batteries or electric accumulators.

November 23, 1889.

18,768. M. IMMISCH. London. Improved arrangement for applying electro-motors to vehicles and for transmitting motion to the axles thereof.

18,779. J. BERESFORD. Manchester. Improvements in material for making wire fencing, applicable also to the manufacture of telegraph wire.

18,795. W. P. THOMPSON. Liverpool. Improvements in or relating to dynamo-electric generators (The Westinghouse Electric Company, United States).

18,817. H. BIRKBECK. London. Improvements in electric mechanism for operating telephone call-bells and annunciators (F. W. A. Schneider and W. C. Keidler, Canada).

18,821. G. GAERTNER. London. Improvements in electric baths or apparatus for applying electricity for medical or other similar purposes.

November 25, 1889.

18,855. F. W. WHITE. London. An automatic attachment for electrical switches, gas and other taps or cocks, valves, &c.

18,897. J. G. S. CUNNINGTON. London. An improved quick-make and quick-break switch for electrical purposes.

18,908. W. C. JOHNSON and S. E. PHILLIPS. Improvements in switches for electrical circuits.

November 26, 1889.

18,939. H. P. HOLT. Manchester. Improvements in and connected with railway and tramway vehicles, and with their propulsion by means of electricity.

18,952. W. HOWSON. Sheffield. Improvements in electrical and automatic appliances and methods for manipulating aeronautic balloon batteries in conjunction with aerostatic, indicating, fulminating, and fumigating repeating magazine batteries, and in shells for same for the purposes of warfare.

18,953. G. MACAULAY-CRUIKSHANK. Glasgow. An improved electrode for secondary batteries of accumulators (W. A. Johnson and J. N. Smith, Canada).

18,966. O. A. ENHOLN. London. Improvements in primary or galvanic batteries.

18,979. W. R. MICHL. London. Improved regulator for electric currents

18,980. W. F. BRADNER. London. Improved means of suspending electric lamps and other suspended objects.

18,989. W. F. SMITH. London. Improvements in secondary or storage batteries.

18,997. A. J. BOULT. London. Improvements in or relating to the connecting of an accumulator battery in alternating current circuit (A. Foeppl, Germany).

19,004. W. WHITE. London. Improvements in suspenders and holders for electric glow lamps.

19,011. J. HOPKINSON. London. Improvements in dynamo-electric machines.

November 27, 1889.

19,079. F. BRYAN. London. Improvements in electrical instruments.

19,080. H. T. CHESWRIGHT. London. An improved construction of plates for secondary or other voltaic batteries.

19,081. R. WREDEN. London. Microtelephonic apparatus for divers.

November 28, 1889.

19,108. W. H. DOUGLAS. Birmingham. An improved instrument for registering electrical currents.

19,129. C. R. BONNE. London. Improvements in electric dry batteries (H. Meinecke, Junr., Germany).

19,142. J. HOPKINSON. London. Improvements in continuous-current transformers of electrical power.

19,155. R. KENNEDY. Glasgow. Improvements in and relating to electro-motors.

November 29, 1889.

19,190. E. L. LOVELL and A. F. LLOYD. London. Improvements in and relating to induction coils and other electro-magnets.

19,195. R. SUMMERS. London. Improvements in and relating to the laying of electric and other wires in streets and roads.

19,199. H. BADCOCK, W. GRUNSELL, and A. WALKER. London. Improved means for the prevention of polarisation in electric batteries.

19,216. F. J. PATTEN. London. Improvements relating to the generation, distribution, and utilisation of electrical currents.

19,220. SIEMENS BROS. AND CO. (Limited). London. Improvements in distributing electricity with alternating currents and apparatus therefor (A. M. Taylor, India).

November 30, 1889.

19,277. L. E. S. CHURCHILL. London. A new or improved apparatus for measuring, indicating, and recording electric currents.

19,283. L. B. MILLER. London. Improvements in apparatus for measuring electricity.

19,285. J. CAMPBELL. Glasgow. New or improved ship's electrical signalling apparatus.

COMPANIES' MEETINGS & REPORTS.

The Gülcher (New) Electric Light and Power Company (Limited).

The second ordinary general meeting of this Company was held at Winchester House, Old Broad-street, on Wednesday, Mr. D. de Castro presiding.

The meeting was a private one, but we have received from the Company the following abstract of the report of proceedings :—

The SECRETARY (Mr. T. C. Morgan) having read the notice calling the meeting,

The CHAIRMAN said that he thought it might be convenient before discussing the accounts to remind the shareholders of what had taken place during the last two years. In January, 1888, the Court of Chancery sanctioned a reconstruction of the Gülcher Company, and on February 23rd an agreement was signed for the sale to the new Company of the old Company's assets for £16,000 in cash and £20,000 in Deferred shares. On February 28th the first prospectus of the new Company was issued. Under that prospectus they attempted to raise £25,000 in Preference shares, out of which they would have had to pay the £16,000 in cash, leaving £9,000 for working capital. That attempt failed. They obtained only £12,000 of subscribed capital, which was largely taken by old creditors under the advice of their friend Mr. Howard Lane, who represented the creditors of the old Company, and whom they could not thank too much for the assistance he rendered in reconstructing it. Matters now remained at a standstill, and no move was made until May, 1888, when a new personage appeared on the scene. That gentleman thought that as they had got such a substantial sum as £12,000 absolutely subscribed, there ought to be some mode of raising the balance and of saving the assets of the Company ; and he suggested that if those who had subscribed the £12,000 were prepared to allow £8,000 of Debenture stock to take precedence of their capital, the Company might issue £8,000 Debenture stock and £12,000 of Preference shares, and so pay the £16,000. He also offered to find £5,000 of that Debenture stock if the scheme were undertaken. Thereupon the Directors of the old company raised £3,000 of the Debenture stock, and on June 10th a prospectus was sent out supported by another circular from Mr. Lane and Mr. Binswanger, urging the carrying out of the new scheme. At the end of July the whole of the £12,000, besides the £3,000 above mentioned, having been subscribed, a special resolution was passed on August 9th, to enable them to issue Debenture stock, a power which they did not then possess. That resolution having been formally registered, the assets of the old Company were on August 31st handed over to the new Company, and on September 1, 1888, the new Company started on its present career. He might tell them that of the £5,000 promised as above, only £500 was ever forthcoming, but in November, 1888, to make a long story short, the deficiency of £4,500 was, with the assistance of Major Cotton and Mr. Wallace, old Directors, found by the Board, thus overcoming their first serious difficulty.

The CHAIRMAN then proceeded to deal with the history of a contract entered into with the Corporation of Wellington, New Zealand, for the lighting of that town, which cost the Company a great deal more than their late manager had estimated. To carry out this contract the Directors invited the shareholders to find £10,000 on Second Debentures. Only £4,500 was at first subscribed, but eventually the balance was obtained, mainly from the Board, and by that means the Wellington contract was completed last September, and was now an income-producing asset. It was by the light of these and other difficulties, which he detailed, that the Directors asked the shareholders to read the accounts submitted, which only brought them down to a date when the New Zealand contract was still incomplete. Under a new *régime* matters had improved greatly, and so far as it was possible for a manufacturing company to say that it had made a profit without taking stock, he believed he might say that Mr. Fricker (the present general manager) had made a manufacturing profit of £2,500 during the last six months. That, if maintained, would be enough to pay the interest on all the Debentures, to pay their working expenses, and leave a dividend on their Preference shares. He explained that the present meeting had been postponed in the hope that certain negotiations which were pending, and which he trusted would turn out for the benefit of the Company, would have been by this time concluded, and he had been anxious to announce their completion at this general meeting. Those negotiations, however, had not yet been concluded, and as the meeting could not be legally postponed any longer, he could say no more than that he hoped to be able to announce the completion of them shortly. In conclusion, he appealed to the shareholders to stand by the Directors. There was a great future for electricity. The times were with them, and he believed they had lived into an era which would be as epoch-making as those which saw the introduction of printing and the utilisation of steam. He then proceeded to analyse the balance-sheet in detail, as well as the profit and loss account, and concluded by formally moving their adoption.

Mr. GOOLDEN seconded the motion. After some discussion of the accounts and the general policy of the Company, the motion was unanimously adopted.

The Directors having retired, resolutions were passed re-electing them all, and re-appointing Mr. Russell Day to be the Company's Auditor.

A vote of thanks was then passed to the Chairman, and the proceedings terminated.

The Maxim-Weston Electric Company (Limited).

The statutory general meeting of this Company was held on Wednesday, at the Cannon-street Hotel, Mr. John Marks having been voted to the chair.

The SECRETARY (Mr. Boyce) read the notice convening the meeting, together with the report of the liquidators appointed to wind up the old Company, an abstract of which is given below.

The CHAIRMAN then said that the only question of interest beyond what was stated in the report, and upon which he would have liked to say something to the meeting, was one as to which his mouth was necessarily closed, namely, the litigation now going on between Mr. Hugh Watt and the Company on the one hand, and between the liquidators and Mr. Watt on the other hand. It would be seen from the report just read that the liquidators had been successful in disputing Mr. Watt's claim to 7,376 shares in the old Company, for which Mr. Watt maintained that he held the certificates. But other shareholders held certificates for some of the same shares, and the liquidators contended that he was entitled to some 3,000 shares less than the number claimed. He (the Chairman) was happy to say that they had succeeded in upholding their contention before the arbitrator (Mr. Frederick Whinney), to whom the matter was referred. The present was merely a formal meeting to comply with the statute. Had the litigation now going on been settled, they would have long since wound up the Company, and there would have been no need to call them together on that occasion ; but as the litigation was not closed, the liquidators were bound to convene a meeting within twelve months after the passing of the resolutions to wind up the Company to report what they had done up to date. He concluded by moving the adoption of the report.

Sir HENRY HOARE asked what money they had in hand, and what work in the way of electric lighting they were doing.

The CHAIRMAN said that the question asked had reference to the new Company only, and did not bear upon the liquidation. He had no doubt, however, that Mr. Godding, the Chairman of the new Company, who was present, would, at the conclusion of the meeting, give any information with reference to the new Company. In further reply to a shareholder, he added that what Mr. Watt was entitled to was 4,416 shares at 1s. 6d., instead of 7,376, but no money would be paid until the litigation now pending was settled.

The report was then adopted.

Mr. JOHN NEWTON proposed, and a Shareholder seconded, a motion to the effect that the report of the liquidators should be printed and circulated among the shareholders of the old Company.

Digitized by Google

Sir HENRY HOARE thought that they should be satisfied with the succinct and reasonable report presented to the meeting, and save themselves the expense of its circulation. He concluded by moving an amendment to that effect.

Mr. NEWTON: How many shareholders are there?

The SECRETARY: 1,720.

Mr. J. JOSEPH seconded the amendment, which on being put to the meeting was lost. The original resolution was then put and carried.

A long discussion followed on the subject of remunerating the liquidators, and eventually, on the motion of Sir HENRY HOARE, seconded by Mr. NEWTON, it was unanimously resolved to grant them 150 guineas on account out of the money at present in the coffers of the Company, pending the conclusion of the litigation referred to, and the winding up of the company.

The CHAIRMAN, as one of the liquidators, returned thanks, remarking that the work imposed upon them had been so onerous that he, for one, if he could have foreseen what was in store for him, would have been exceedingly reluctant to undertake the duties. They would complete the liquidation as speedily as possible after the conclusion of the litigation.

ABSTRACT OF REPORT OF THE LIQUIDATORS.

By special resolution the liquidators were authorised to enter into an agreement with a new Company, to be named the Maxim-Weston Electric Company (Limited), for the sale to such new Company of the business and property of the old Company. The new Company was registered January 17, 1889, and the liquidators have entered into the agreement with the new Company which was sanctioned by the shareholders of the old Company. In pursuance of that agreement, the new Company has taken possession of the business and property of the old Company, with the exception of certain claims to be hereafter referred to.

The new Company have paid debts and liabilities of the old Company, and of the liquidators, amounting to £4,180. 14s.

The new Company have allotted to shareholders in the old Company 262,536 shares of 3s. each in the new Company, with 2s. each credited as paid thereon in exchange for shares of the old Company.

Proceedings were taken in the Chancery Division to restrain the liquidators from carrying the agreement into effect. These proceedings were compromised. Arbitration proceedings were afterwards instituted. Ultimately the liquidators arranged to pay to the dissentient shareholders 1s. 6d. per share, and the new Company have paid on this account the sum of £1,813. 14s. 6d.

Of the 312,000 shares to be allotted to the liquidators or their nominees by the new Company 49,464 shares were not applied for by the shareholders of the old Company. Of these shares 11,845 have been sold by the liquidators, and have realised the sum of £868. 17s. 6d.

With reference to a dispute between the liquidators and Mr. Hugh Watt as to the number of shares in the old company to which he was entitled, such dispute was referred to arbitration by Mr. Whinney, who decided that Mr. Watt was entitled to 4,416 shares in the old Company, and that he would be beneficially entitled to a further 2,710 shares if he paid the sum of 5s. per share. Further, that Mr. Watt pay to the liquidators the sum of £50 towards their costs of the reference.

The liquidators regret to state that of the £9,769. 19s. 9d. appearing at the date of the liquidation as book debts, and which were nearly all included as good book debts in the 1887 balance-sheet, they have only been successful in recovering £1,143. 5s. 3d. This is owing to the fact that many of the accounts were disputed, and a very much smaller sum than that stated in the Company's books had to be accepted in order to effect any settlement.

As litigation is still pending with Mr. Watt, the liquidators refrain from further comment upon them.

Metropolitan Electric Supply Company (Limited).

The following is the report of the Directors of this Company, to be presented to the second ordinary general meeting of shareholders, to be held at Winchester House, Old Broad-street, E.C., to-morrow (Friday) at 12 noon. A full report of the proceedings will appear in our next issue:—

1. The Directors have satisfaction in submitting the statement of accounts to September 30, 1889, and in informing the shareholders of the progress made by the Company.

2. Since the last general meeting important rights have been granted to the Company, with the sanction of the Board of Trade, and confirmed by Parliament. Extensive installation works have been completed, and are now supplying the electric light, and other works of the same character are in progress, and approach completion, for the efficient lighting of the areas assigned to the Company. These areas are estimated to include in the aggregate about 35 miles of streets, a large number of which run through some of the wealthiest portions of the metropolis.

3. The existing demand for the electric light far exceeds the Company's power of supply, even if its authorised capital had been all called up and expended on installation works, and the Directors have under their consideration the issue of debentures at a moderate rate of interest, so as to avoid increasing the share capital at present. If, however, the anticipations of the Directors are realised, there seems little doubt that the share capital of the Company will have to be considerably augmented. The Chairman, in the evidence he gave before the Board of Trade inquiry, stated that, if the Company were as successful as he expected, its share capital of £500,000 would have to be increased four-fold, and the present prospects of the Company, judging from the actual applications for the light recorded in its books, point to this estimate being verified, and to a highly-satisfactory dividend being earned.

4. The largest item of capital expenditure is that incurred upon the erection of the stations which are described in paragraph 10.

5. Since the last general meeting, the Board of Trade, acting under the powers conferred upon that department by the Electric Lighting Acts, have held an official inquiry into the applications by this and other companies for Provisional Orders and licences. This inquiry lasted through the month of April, and resulted in a valuable report by Major Marindin, the Board of Trade Inspector, wherein he recommended that there should be allotted to this Company the following areas:—

Under the Mid-London Order.—The whole of the areas comprised in St. Giles-in-the-Fields; St. George, Bloomsbury; St. Andrew, Holborn-above-Bars; St. George-the-Martyr; St. Sepulchre, Saffron-hill; Hatton-garden; Ely-rents and Ely-place; the Liberty of Glasshouse-yard; St. Anne, Soho; St. Paul, Covent-garden; St. John the Baptist; Savoy, or Precinct of Savoy; St. Mary-le-Strand; St. Clement-Danes and the Liberty of the Rolls; together with the extra-parochial places known as the Charter House, Gray's-inn, Lincoln's-inn, Staple-inn, and Furnival's-inn.

Under the West London Order.—The whole of the parish of St. Marylebone.

Under the South London Order.—The whole of the parishes of St. Mary Lambeth; St. Leonard, Streatham; and Clapham.

Under the Bill.—A portion of the parish of St. Martin-in-the-Fields.

The Directors decided not to proceed with the South London Order, but propose making a fresh application for it, when they hope to make satisfactory arrangements with the local authorities with whom they were not able to settle terms within the time at their disposal.

A larger portion of St. Martin-in-the-Fields than that recommended was afterwards conceded. The remaining Orders were confirmed by Parliament during the last Session.

6. The result of this legislation has been to give the Company the right of supplying electricity within the above-named areas, and if the Board of

Trade, to avoid the frequent breaking up of streets and interference with traffic, adhere to the principle laid down, that not more than two companies shall be recommended for each district—one restricted to the use of the alternate-current transformer system, and the other to the use of the continuous-current system—future competition will be limited.

7. This principle, valuable in itself and of great service both to this Company and the public, could only be upheld after a full and exhaustive inquiry into the means of the various companies and their proposed methods of supply. This necessarily involved considerable delay and expense, both the London County Council and the local authorities taking part in the inquiry conducted by Major Marindin, and also in the subsequent proceedings before the Committees of both Houses of Parliament. The subject has been thus thoroughly thrashed out, and the large and important areas assigned to this Company will be supplied with the electric light under satisfactory conditions, which have, moreover, the advantage of both Departmental and Parliamentary sanction.

8. The Company is seeking powers to supply other areas of the metropolis, and has given the requisite notices to that effect.

9. It must be understood that the position of the Company with regard to its allotted areas has been only recently sufficiently assured to warrant the Directors in completing their system of supply. It was not until after the Royal Assent had been given to the Confirmatory Acts in August last that the Company was authorised to break up the streets for the purpose of laying underground mains. Notwithstanding this, it will be seen by the following list of central stations that good work has been done, and that the demands on the recently completed station at Sardinia-street are already so great as to necessitate a duplication of the existing plant.

10. CENTRAL STATIONS.—For supplying electricity in the Company's areas, the following stations have been erected, are in course of erection, or are about to be erected :—

(1) *Erected and Working.*—(*a*) Whitehall Station (continuous current).—This station is now about to be fully employed, the demands for current being in excess of its capacity, regard being had to the requirements of Whitehall-court when completed.

(*b*) Sardinia-street, Lincoln's Inn Fields (Alternate-Current Transformer).—This station commenced working on September 21st last. The demand for light being in excess of the present capacity, the Directors have lately decided to order the completion of the station, by which its power of supply will be more than doubled.

(*c*) Rathbone-place, Oxford-street (Alternate-Current Transformer).—A small station on this site was purchased in February last as a going concern. Arrangements were made for the erection of a larger plant, and a portion of the new machinery is now running. The full capacity of this station is also fully engaged.

(2) *In Course of Construction.*—(*d*) South Mews, Manchester-square, Marylebone (Alternate-Current Transformer).—A large station is in course of construction on this site, and will, it is expected, commence working next spring.

(*e*) Waterloo Wharf (Alternate-Current Transformer).—The machinery for this station is in a forward state, but the Directors have delayed erecting buildings owing to negotiations, which are not yet concluded, with the London County Council.

(3) *About to be Constructed.*—(*f*) A station within the Strand District (now being partially supplied from Sardinia-street).

And conditionally on the Company obtaining the powers for which they are seeking :—

(*g*) A station to supply the western portion of the City ; and

(*h*) A station to supply Paddington.

11. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., retire, and offer themselves for re-election.

NEW COMPANIES REGISTERED.

CAMBORNE GAS COMPANY.—This Company has been registered to supply gas, electricity, or any other illuminating agent, in and around Camborne, Cornwall, purchasing for that purpose the existing Camborne Gas Works at Tuckingmill, on the terms of an agreement of November 29, 1889, made with John Thomas, and unregistered. Capital £10,000, in £5 shares.

GAS CONSUMERS' PROTECTIVE ASSOCIATION (LIMITED).—This association was registered on the 11th inst., with a capital of £1,000, in £1 shares, whereof 20 are founders' shares, to protect consumers of gas, electric light, or power, or water against loss or damage in connection with the supply or consumption thereof. Solicitors, Messrs. Burn and Galloway, 50, Gresham-street.

HEATHLEY, JANISCH, AND CO. (LIMITED). — This Company was registered on the 14th inst., with a capital of £3,000, in £1 shares, to trade as chemists, druggists, and dealers in proprietary articles, and in all kinds of electrical and scientific apparatus. Solicitors, Messrs. Watson and Dendy, Newcastle-on-Tyne.

THE KELVINSIDE ELECTRICITY COMPANY.—This Company has been formed, with a capital of £10,000 in £1 shares, and has been incorporated for the purpose of supplying electricity in Kelvinside. The necessary application, notice of which has been given to the local authority, will be made for a Provisional Order under the Electric Lighting Acts, and should the Provisional Order be obtained from the Board of Trade, and confirmed by Parliament, it is proposed to at once provide and equip an electricity station for the supply of electricity to the district of Kelvinside.

THE NORTH AFRICAN GAS SYNDICATE (LIMITED).—This syndicate has been registered, with a capital of £30,000 in £1 shares, to carry on the business of a gas or electric light company in the towns of Algeria and other parts of Northern Africa.

TRUST AND LOAN COMPANY OF CHINA, JAPAN, AND THE STRAITS (LIMITED).—Amongst the various objects for which the Company is formed is "take over or otherwise acquire" securities of telegraph and similar undertakings in China, Japan, the Straits Settlements, or elsewhere.

CITY NOTES, &c.

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company announces the payment on January 14th next of interest of 3s. per share, less income-tax, being at the rate of 6 per cent. per annum on the Preference shares of the Company, for the quarter ending December 31st, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income-tax, in respect of profits, for the quarter ended September 30th. The register of transfers will be closed from January 7th to 14th, both days inclusive.

EASTERN EXTENSION AUSTRALASIA AND CHINA TELEGRAPH COMPANY.—This Company announces that the coupon on their Five per Cent. Australasian Government Subsidy Debentures, due on January 1st next, will be paid on and after that date at Messrs. Barclay, Bevan, and Co.'s, 54, Lombard-street, E.C. Coupons must be left three clear days for examination.

ANGLO-PORTUGUESE TELEPHONE COMPANY.—Coupon No. 4 of this Company's Six per Cent. Debentures will be paid, less income-tax, by the Alliance Bank, Bartholomew-lane, on and after January 1st next.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 13th amounted to £5,605.

GREAT NORTHERN TELEGRAPH COMPANY.—A half-yearly interim dividend at the rate of 5 per cent. per annum on the shares of this Company will be paid by Messrs. Hambro and Son on January 1st.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY.—Messrs. Robert A. MacLean and Co. announce that the coupons, due January 1 next, on the Six per Cant. First Mortgage Bonds of this Company will be payable by them on and after that date.

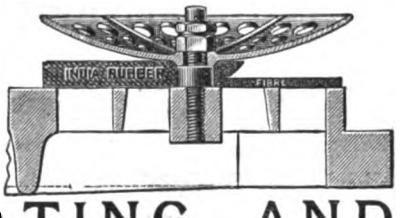
TELEPHONE COMPANY OF AUSTRIA.—Coupon No. 10 of this Company's Five per Cent. Debentures will be paid, less income-tax, by Messrs. Martin and Co., 68, Lombard-street, on and after the 31st instant.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 13th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,017.

WEST INDIA AND PANAMA TELEGRAPH COMPANY.—The receipts o this Company for the half-month ended December 15th amounted to £2,803, as compared with £2,836 in the corresponding period last year, a decrease of £33.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept 1888.
"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I lconti lc get them from you as required.—Yours faithfully, JAMES WESTOLL."

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 606.—Vol. XXIV. FRIDAY, DECEMBER 27, 1889. Price Fourpence.

NOTES.

We have received the following important cablegram from our New York correspondent:—

> "It is cabled here that the London edition of the *New York Herald* says that New York is going to abandon electric lighting altogether and return to gas. Give this statement your strongest, most emphatic, and most unqualified denial. It is absolutely without truth. Electric lighting is gaining ground here faster than ever, and next year there will be at least 25 per cent. more electric lights in New York than now. Every large new building, without exception, is putting them in. As for the streets along which overhead arc wires have been cut down, many of the storekeepers are putting in their own arc lights, and there is already a marked reaction against the wire-cutting dictated by local political intrigues. The *New York Times* calls for a resumption of arc lighting, and the leading evening paper, the *Evening Post*, says no great city which has once been lighted by electricity will go back permanently to gas. The abolition of the New York Board of Electrical Control is called for even by papers that have been led to approve their crusade against overhead wires. Give the widest publicity to this contradiction of these malicious reports, which appear to electricians on this side of the water to be dictated by a mercenary purpose, and it is thought in some quarters that the opportunity has been seized by the gas interest to make a last desperate effort, for although the crusade was nominally begun against high-tension wires the axemen have even been cutting down circuits carrying only low-tension direct currents of 125 volts or less."

Our New York correspondent this week refers at considerable length to the question of the origin of the recent disastrous fire in Boston. The information contained in his cablegram of December 6th was sufficient to make the electric current theory appear more than doubtful, and his present letter ought to complete the process. It is, we hope, not too much to expect that after the conclusive manner in which electricity has been proved "not guilty" in this matter, fewer statements will be made at the meetings of local authorities to the effect that "the big fire at Boston, which was undoubtedly caused by electricity, renders it imperatively necessary," &c. &c.

Photo-electric and actino-electric methods of producing charges have claimed the attention of physicists from time to time. The researches of Becquerel on the currents produced by immersing in water two metal plates, one of which is then exposed to light, are well known. The experiments of Prof. Minchin about ten years ago will be within the memory of a number of our readers. Then about two years ago Hertz made the discovery that light falling upon a negatively electrified body causes a dissipation of the charge. This effect has been studied in greater detail by Wiedemann, Righi, and others. The latest researches on this head are by Prof. Stoletow (of St. Petersburg), an account of which we publish in another column, who has obtained some very striking results. He interposes in a circuit, with a galvanometer and a battery, an air condenser, consisting of two metal coatings, one of which is of sheet metal, the other of metallic gauze. If this condenser is so connected up that the gauze is positive and the plate negative, then, on illuminating the plate, through the gauze, by turning on an arc lamp, a current is obtained. The action is almost imperceptible, however, when the poles are interchanged. He proves that the effect is due to ultra-violet waves, and can be cut off by the interposition of sheets of glass, ice, or films of water.

In two recent issues of the *Electrical Review* of New York we find a proposed arrangement of an alternate-current generator and its circuits, which is described as a new three-wire system of distribution. It is due to Lieut. Patten, and it is claimed for it that it presents several features which enable effects to be obtained which usually accompany direct-current only, while at the same time it gives also the ordinary alternate-current effects. Briefly, it is proposed to commute the alternate current at the generator, and to send all the positive waves in one direction through a wire, M^1, all the negative waves through another wire, M^3, while a third or middle wire, M^2, is to act as a common return for both waves. It is suggested that direct-current apparatus may be placed in either the M^1 or the M^3 circuit, or that both these circuits may be included in the same direct-current apparatus—of course, the proper directions to give the same directive effect being observed; while alternate-current apparatus may be placed in the common return M^2. Without going into the details of the proposed arrangement of this system in connection with secondary batteries, electric motors, and arc lamps—which details show that the author of the scheme is not very familiar with the requirements of practical work with these apparatus—it will be evident that all the "direct current" effects aimed at could be much more simply obtained with two than with three wires. There is absolutely no advantage in the use of three wires in this way, so far as our reading of the proposal goes, while there is the great disadvantage that in either of the circuits M^1 or M^3 there is not only a discontinuous direct current, but the discontinuity amounts to having idle

Digitized by Google

ntervals between the successive waves equal in duration to the waves. In order to get even an approximately continuous direct current it would therefore be necessary to use both circuits in conjunction, and this only gives in a very roundabout way what would be obtained by using an ordinary commutator, as has often been proposed, and sending the alternate current after commutation through an ordinary single circuit.

It will be seen that this system affords no justification for one of the principal claims put forward on its behalf, namely, that it renders possible the use of all ordinary electro-magnetic devices by means of alternate currents without commutation. Many good things come to us from across the Atlantic, and for these we are thankful; but we must confess to a desire that it did not so often fall to our lot to have to criticise the immature, ill-considered, or impracticable schemes which so often appear in our American contemporaries, and we think it would be both in the interests of those journals and of the too-enthusiastic authors of some of these proposals if the matter were critically examined before being accorded the dignity of print; or, if there should be any insuperable difficulty in this course, that at least sufficient time should be allowed, before making announcements, to enable some practical trials to be made.

It would seem as if the Paris Municipal Council are not to be allowed any peace until the unfortunate Ferranti alternators at the Halles Centrales are ejected to make room for machines entirely French. At its last meeting the Council was induced to order the Commission Technique to immediately furnish a report as to its proceedings after the Council's resolution of December 31st last, relating to the use of foreign material. MM. Dandeu and Naze, whose 220-kilowatt alternator, it will be remembered, failed to find favour in the eyes of MM. Potier and Carpentier, who undertook to test it for the Municipal Council, are again to the front with a petition for a new trial. The Société Ferranti, in the vain hope of appeasing its enemies, has armed itself with a certificate setting forth that the alternators in dispute were actually built at the Cail works. In answer to this proof of the patriotic origin of the offending machines, our French contemporaries reply epigrammatically, but somewhat pointlessly, that "*Une bonne renommée vaut mieux qu'un certificat de vertu.*" It is evident that nothing short of the sacrifice of the Ferranti machines will restore the French electrical firms to their wonted equilibrium.

That strikes at the best are regretable incidents, and the present method of resorting to arbitration only under stress of circumstances is unsatisfactory, is, we believe, generally admitted. The efforts of the Council of the London Chamber of Commerce to devise a more civilised way of settling labour disputes are, therefore, worthy of every support. Appended to the Interim Report of the Labour Conciliation Committee appointed by the Council is a rough draft of a scheme which, coming from anyone but business men, would be dismissed as Utopian, but which, nevertheless, may prove workable.

The Committee propose that a permanent Committee representative of both capital and labour should be appointed to deal with questions arising out of labour disputes within the Metropolis. Whenever opportunity offers the Committee would in the first instance place the rooms of the Chamber of Commerce at the disposal of the disputants for the purpose of a friendly conference, and in the event of the failure to arrive at an amicable settlement the Committee would then offer to mediate or to select arbitrators. The Committee would further endeavour to promote the formation of Councils of Conciliation amongst the various trades of London, to be composed of employers and workmen, and it is suggested that such Councils might be affiliated to the London Chamber of Commerce.

A scheme of this nature will not fail to commend itself to employers. But it takes two to effect a conciliation as well as two to make a quarrel, and workmen have hitherto been inclined to view all such suggestions as the above with considerable suspicion, and before Mr. S. B. Boulton's proposals can become accomplished facts it will be necessary to disarm this suspicion by making the Committee thoroughly representative of the working classes—and such, indeed, we understand, is the firm intention of the Council. *Employés* will also have to be educated to the notion of reciprocity and compromise. At present their attitude is somewhat of the all-take-and-no-give character, and although perfectly ready to share the increased profits, they have up to the present generally claimed to be exempt from the reverse process.

"The Junior Engineering Society" visited the Victoria Works of the Brush Electrical Engineering Company on Wednesday, the 19th inst., and were shown over the whole of the departments. They were shown the manufacturing operations connected with the construction and trial of Brush dynamos, arc lamps, Victoria dynamos, the Brush Company's engines, a large number of which were being fitted with Victoria dynamos, principally for ship-lighting, Mordey-Victoria alternators and transformers of several sizes, Victoria motors for tramway and other work, and, in short, the manufacture of all kinds of electrical and engineering apparatus manufactured by this Company. In the testing department, which is provided with two 70 horse-power engines, machines of several kinds were being run, and the visitors were particularly interested in an alternator running on transformers, some of which were supplying incandescent lamps, while others were working on the Brush alternate-current arc lamps. The party evidently found their visit very interesting, and no doubt were impressed with the important position now being taken by electrical engineering.

The *soirée* given last week by the City and Guilds Old Students' Association, at the rooms of the Institute of Medical Electricity, although characterised by a somewhat strange combination of scientific and terpsichorean amusements, was a decided success. In one room of the Institute there was a formidable display of electro-medical apparatus, and in another the phonograph, which, like the poor, is ever with us, performed to its

Digitized by Google

own and everyone else's complete satisfaction. Mr. NEWMAN LAWRENCE lectured as pleasantly as the subject permitted on "Some New Forms of Electric Treatment," and an excellent concert restored the spirits of those who did not take kindly to the very light dose of medical electricity which was administered between the hours of nine and ten. Over a hundred persons were present, and dancing was energetically kept up until the necessity of catching last trains brought the evening's entertainment to a close. Since the Institution of Electrical Engineers inaugurated public dinners we have been inclined to believe in the reality of the present revival of electrical activity, and now that the Old Students have taken to dancing our last doubts are dissipated.

THE appeal of Mr. JOSEPH FREDERICK LEESON against the decision of Mr. Justice NORTH, which we recorded in our issue of December 20th, came on for hearing on Saturday last before Lords Justices COTTON, BOWEN, and FRY, who were unanimously of opinion that the General Medical Council acted within its rights in erasing Mr. LEESON'S name from the register of general practitioners. Lord Justice FRY, however, differed from the other members of the Court upon the question of the competency of the Council, holding that the fact that two of the judges were members of the Medical Defence Union was sufficient to invalidate the proceedings of the Council.

WE have received from Mr. HAROLD P. BROWN a circular letter containing a copy of the report and recommendations of the Health Department of New York, upon what they term dangerous systems of electric lighting. It was at one time thought that this crusade of Mr. BROWN'S was undertaken in the spirit of purest patriotism. How erroneous this impresson was cannot, we think, be better shown than by quoting the concluding sentence of the present letter:—"I therefore feel that this controversy has demonstrated my ability and energy, and respectfully ask to serve you if you are contemplating an investment in electric light or power systems: if you need expert examinations or advice concerning apparatus; if you wish lights tested and compared with contract requirements; if you wish dangerous features pointed out and corrected, or need expert assistance in patent or civil cases."

WE are glad to be able to contradict, on the authority of Signor ENRICO BIGNAMI, the editor of our esteemed Milan contemporary, *l'Elettricità*, the announcement which recently appeared in a contemporary of the death of Prof. PACINOTTI, of Pisa. The mistake, no doubt, arose from the fact that the great electrician's father died a few weeks ago.

Florence.—Particulars with regard to a proposed concession for the electric lighting of Florence will be found in our Trade Notes column.

L'Electricien.—Our esteemed contemporary *l'Electricien* announces that it intends to celebrate the tenth year of its existence by doubling its size.

Leeds.—The Highways Committee of the Corporation of Leeds have decided to invite general competition for the working of the entire tramway system of the borough.

The Electric Welding of Iron Pipes.—The McKeesport National Tube Works are introducing electric welding both for large and small iron pipes, for uniting the edges of the bent metal.

The Protection of Rubber Trees.—It is reported from Guatemala that a stringent law has been enacted there for the protection of rubber trees from careless bleeding, and that this law being strictly enforced.

Central Telegraph Staff.—On Tuesday the staff of the Central Telegraph Office held a meeting at the Foresters' Hall, under the presidency of Sir J. H. Puleston, M.P., for the promotion of civil service interests.

Warsaw.—Consular reports say that electric light installations are becoming very numerous in Warsaw, but they are generally contracted for by foreigners. Austria and Germany are being most concerned in the business.

The Society of Arts.—Sir Douglas Galton, K.C.B., F.R.S., will shortly read a Paper before this Society upon "The Sliding Railway," and Prof. S. P. Thompson upon "The Organisation of Secondary and Technical Education in London."

The Board of Trade.—The Railway and Electric Lighting Departments of the Board of Trade have become so large that it has been found necessary to provide other buildings for the office. The department will shortly remove to 8, Richmond-terrace.

The Sprague Motor Patents.—The Allgemeine-Elektricitäts-Gesellschaft, of Berlin, have secured the Sprague motor patents for Germany, Russia, Austria, and some other countries. The short line between Florence and Fiesole is being built by this Company.

Automatic Electric Lamps.—The latest company to adopt the "nickel in-the-slot" system of railway carriage lighting is the District Railway Company, who are fitting their carriages with electric lamps giving half an hour's light for the sum of one penny.

The City and Southwark Subway.—The experimental train on the Southwark Subway electric railway has now been running for about a fortnight successfully over a portion of the route, and it is anticipated that the line will be opened to traffic about next March.

Calvert's Mechanics' Almanack.—The 1890 edition of this useful little book is, as usual, full of practical hints for mechanics and others. A brief reference to electric lighting and transmission of power and to electric welding would, we think, greatly add to the value of the almanack.

The "Gymnote."—The accounts given in several papers of some recent performances of the electric submarine boat "Gymnote," at Toulon, show that this boat, the design of which is due to Commander Krebs and M. Zédé, is realising some of the sanguine anticipations of its inventors.

Field-Telegraph Work.—The work of laying the field-telegraph lines for the Chin-Lushai Expedition, says *Indian Engineering*, is making satisfactory progress. Permanent offices will shortly be opened at Lungleh on the Chittagong side and at Gungaw on the border of the Southern Chin country.

Telegraphing to Moving Trains.—The system of telegraphing between moving trains and railway stations is rapidly becoming general in the United States. The Pennsylvania Railway Company now telegraphs Stock Exchange quotations to the express trains running between New York and Chicago.

Swansea.—At the last meeting of the Swansea Town Council, it was resolved to appoint a Sub-Committee to prepare specifications and receive tenders for the purpose of lighting by electricity the streets in Schedule A of the Swansea Lighting Order. The Committee was empowered to engage the services of an electrical engineer.

Marylebone Vestry and the Tramway Schemes.—At a meeting of this Vestry last week, it was decided, on the recommendation of the Parliamentary Committee, to oppose the London Central (Subway) Central Railway Bill and the Central London Railway Bill, the inhabitants of Oxford-street agreeing to contribute a moiety of the expenses.

The Railway Diary and Officials' Directory.—We have received from Messrs. M'Corquodale the "Railway Diary and

Digitized by Google

Officials' Directory," and the "Railway Almanack." The Diary and Directory contains a quantity of useful information, particularly for those wishing to communicate with the *personnel* of the great railway systems throughout the kingdom.

Alzano.—An electric lighting company which was recently formed at Alzano, near Bergamo (Italy), has given a contract to the Italian Edison Company for the erection of the entire plant, consisting of two 50-kilowatt 2,000-volt Zipernowsky alternators. The station is situated one and a-quarter miles from the town, and the necessary motive power is supplied by a waterfall.

Appointment Vacant.—The Governors of the Heriot-Watt College, Edinburgh, are about to appoint a Professor of Physics and Electrical Engineering. Applications for the post must be sent to the Treasurer of George Heriot's Trust, 20, York-place, Edinburgh, on or before January 20, 1890. The salary will be £400 per annum. Further particulars are given in our advertisement pages.

The Column Printing Telegraph Patents.—The Comptroller of Patents last week gave his decision in the case of the opposition of the Exchange Telegraph Company to the grant of letters patent for a column printing telegraph instrument, owned by the Column Printing Telegraph Syndicate (Limited), in favour of the latter. The patent for the column printing machine will accordingly be issued.

Lectures on "Electricity."—On Friday evening last between 600 or 700 persons assembled in the New Baths, Battersea, to hear Mr. W. Lant Carpenter deliver the third of a series of lectures on "Electricity," which are being given in connection with the Battersea Polytechnic. In consequence of the success of this series of lectures, the Polytechnic Committee have decided to arrange for ten additional scientific lectures on kindred subjects being given.

Fire in the City.—An alarming fire broke out on Christmas morning in Charterhouse-square, London, E.C., in which is situated the building occupied Mr. S. Z. de Ferranti. From accounts received, we are pleased to say that nothing has happened which is likely to seriously interfere with the regular course of business, although the fire was one of the most extensive that has happened in the City of London for some years. The fire did not originate in the premises occupied by Mr. Ferranti, but at those of an adjoining printers.

A New Insulating Material.—According to the *Chronique Industrielle*, another new insulating material has just been produced. It consists of one part of Greek pitch and two parts of burnt plaster, by weight, the latter being pure gypsum raised to a high temperature and plunged in water. The mixture, when hot, is a paste, and can be applied by a brush, or cast in moulds. It is amber-coloured, and can be turned and polished. Its advantage is said to be its endurance of great heat and moisture without injuring its insulating properties.

National Telephone Electrical Society.—At the meeting of this Society on Friday evening last, Mr. Loghes, the construction inspector of the Midland District of the National Telephone Company, read a Paper on "The Construction and Maintenance of Telephone Lines." The lecturer dealt with the erection, arming, and earthing of poles, standards, and other fixtures; the regulation of dip, or "sag," and the "twist" method of running metallic circuits. A neat model of a complete route on the "twist" method assisted the lecturer in his explanations.

Presentation to Mr. T. Parker, of Wolverhampton.—Mr. T. Parker, of the well-known Elwell-Parker Works, was presented on Saturday last, at the Drill Hall, Wolverhampton, with a silver tea service and a framed illuminated address. The presentation was made as a mark of the esteem in which Mr. Parker is held by the *employés* of the Electric Construction Corporation, many of whom were in the employ of the firm of Elwell-Parker (Limited) before the transfer to the Construction Corporation. The Mayor of Wolverhampton presided, and the proceedings throughout were of the most cordial character.

Technical Education in New South Wales.—The Government of New South Wales has adopted an entirely new scheme of technical education. The present Board of Technical Education is to be abolished, and technical schools will be placed under the direct control of the Education Department. A sum of £50,000 is to be expended in the erection and equipment of a new Technical College and Museum in Sydney, while branch technical schools will be established throughout the country districts. It is estimated that £50,000 will be required annually to carry out the new arrangements.

The Electric Lighting of the Russian Imperial Train.—The Russian Imperial Train has recently been fitted with the electric light. The train comprises some 12 or 13 carriages, one of which contains a "Nobel" boiler, a Brotherhood engine, a 12-unit dynamo, a petroleum reservoir, and a water-supply tank. The electric installation, which has been carried out by the Jablochkoff Company, of St. Petersburg, comprises 253 30-volt 30-watt incandescent lamps, run direct off accumulators distributed in three of the carriages. The light is moderated by interposing a frosted or tinted glass shade. The accumulators ensure light for 20 hours, but they can, if necessary, be charged during the journey.

Proposed International Memorial to James Watt.—A proposal has been set on foot in Greenock to erect there an international memorial to James Watt. The local Philosophical Society has taken the matter in hand, and has appointed an influential committee, to co-operate with a large committee under the auspices of the Town Council, to approach scientific and engineering societies in London, Glasgow, Edinburgh, and other large centres, with the object of securing their sympathy and practical co-operation. Various suggestions as to the form the memorial should assume have been under consideration, and one of the proposals mentioned is that a thoroughly-equipped technical school should be erected in Greenock.

The Dangers of Electricity.—In view of the present outcry about the dangers of the electric light, and the many absurd restrictions which are being proposed, it is interesting to recall the protest drawn up by the Royal College of Bavarian Doctors in the early days of railways. They stated that travel in carriages drawn by a locomotive ought to be forbidden in the interest of public health. The rapid movement would produce among the passengers the mental affection known as *delirium furiosum*. Even if travellers were willing to incur this risk, the Government should protect the public. A single glance at a locomotive passing rapidly was sufficient to cause the same cerebral derangement. Consequently it was absolutely necessary to build a fence 10ft. high on each side of the railway.

The "Faraday" Electric Works.—The second annual gathering of the *employés* and friends of the "Faraday" Electric Works took place in the Masonic Hall, Burndyke, on Friday last, Mr. Wm. M'Whirter, M.I.E.E., presided. The Chairman, in the course of his remarks, said he was glad to be able to say that their progress last year had been considerable. Looking over the list of orders executed and those on hand, he found that their output would be something like treble what it had been in any previous year. A year ago they were seriously considering what was to be the future form of the dynamo. If the results of further experiments were the same as those of the first experiment, their dynamo of the future would be a dynamo where wrought iron would be abandoned in favour of cast iron.

The Jamaica Exhibition of 1891.—It is proposed to hold in Kingston, Jamaica, in the year 1891, an exhibition of the products, manufactures, and works of art from the island itself, and works of art, machinery, and industrial and agricultural products from the United Kingdom, and other countries and colonies. The exhibition, which will be opened on January 27, 1891, will remain open for not less than three months, and will be under the management and conduct of the Commissioners, at the head of whom is the Governor. The regulations for exhibitors are now published, and from these it appears that applications for space must be in the hands of the secretary by May 1, 1890. Communications and applications for forms and regulations must be addressed to Mr. C. Washington Eves, 1, Fen-court, E.C.

The Violle Light Standard.—A new pattern of the Violle Light standard has recently been devised by M. Carpentier. In the new arrangement, the fusion of the platinum is effected by a jet of mixed illuminating gas and oxygen, which plays

Digitized by Google

upon the platinum ingot placed in a hollow in a block of lime. This block is in two parts, the upper part (through which the gas jet passes) being movable by means of a handle. The lower part of the block is arranged so that it can be slid from under the upper block to a position beneath a shield with a hole in the centre, whose area is 1 square centimetre. An inclined mirror above this shield enables the surface of the glowing platinum to be seen at right angles to the same. The handle enables the upper half of the block to be moved aside, so that it can be seen if the platinum is melted.

The Post Office and the Use of the Telephone.—The Leicester Town Council, the Chamber of Commerce, and the Trade Protection Society recently appealed to the Postmaster-General on a very important point connected with the use of the telephone in cases of fire or riot. The question arose in consequence of a delay in the transmission of an alarm of fire. The local post office officials decided that as the fire did not originate on the premises of the renter of the telephone he was not entitled to use the telephone for the purpose of informing the fire brigade, the telephone communication being restricted "to his own business and private affairs." The Postmaster-General has now written to say that, while the use of the telephone is restricted to the renter's own private and business affairs, the department will be only too glad to allow its use to convey information concerning the outbreak of fires or of rioting.

Courses of Lectures.—Our readers will be pleased to learn that Prof. Perry's special course of 13 lectures on the "Differential and Integral Calculus and its Applications in Mechanical and Electrical Engineering," which proved so successful last year, will be repeated at the Finsbury Technical College, Leonard-street, E.C., the date of the first lecture being January 7th. Students are expected to know elementary algebra and trigonometry. It is well known to be Prof. Perry's view that all practical engineers use the notions and methods of the calculus in their daily work: those of them who think themselves ignorant of the calculus are merely afraid of the symbols $\frac{dy}{dx}$ and $\int y \, . \, dx$——A course of lectures will also be given, at the Central Institution, Exhibition-road, S.W., by Prof. W. E. Ayrton, on "Electrical Technology." The lectures will be given on Mondays and Wednesdays, commencing on January 15th next.

Incandescent Lamps on Buoys.—A recent report, made by Captain Millis, of the United States Lighthouse Board, in relation to the electric lighted buoys at the Gedney's Channel entrance to New York Harbour, states that a year's service shows that the system is a practical success. The buoys withstood heavy storms without drifting from their positions, and not more than two lamps out of six were extinguished at any one time. On one occasion a buoy was run down by a vessel and entirely submerged without injury. Some trouble has been experienced from moisture getting through the lamp sockets and destroying the connections, but a new form of lamp has been devised which promises to be free from this objection. It has been found that the life of lamps made with red glass globes was much shorter than that of the uncoloured ones, an effect which was attributed to the interception of a greater portion of the heat radiated from the carbon filament, and lamps with bulbs of clear glass are now used on all the buoys, lanterns lined with red glass being used to produce the red lights. Captain Millis notes the fact that a building on shore very near the buoys was twice struck by lightning while the buoys and their connecting cables were uninjured.

The Administration of Drugs by Electricity.—At a recent meeting of the Harveian Society, Dr. Cagney said that experiments by Eulenburg, von Bruns, and Hermann Munk had shown that certain drugs could be made to pass through animal tissues between the poles of a galvanic current, and he himself had used iodide of potassium in this way for the cure of lead palsy. Only very small doses, however, could be administered through the skin. The method was best adapted for the treatment of diseases of the skin and mucous membranes, or of small tumours immediately beneath them. In the application of the method a very strong current was not needed, but a sufficient current density was required, and the tissues under treatment must be brought directly in the path of the current. The electrodes might be either sponges holding solution of iodide of potassium or a modification of Dubois's conducting tubes filled with the fluid. The electrodes should be of large surface area. The fluid should be a saturated solution of iodide of potassium, and it ought to be supplied, where possible, at both poles. Where this was not possible the solution should be at the negative pole. The current should be passed for 10 to 15 minutes, and its strength would be determined by circumstances. Its direction should be reversed every minute. Mr. Juler remarked that the method had given excellent results.

Smith's Method of Making Amalgamated Storage Battery Plates.—One of the methods which has been largely employed in the past in order to prevent the oxidation of the supporting plates in a storage battery has been the amalgamation of the plate. This has generally been effected by adding to the molten lead a certain quantity of mercury. This process, however, does not always give uniform results, on account of the volatilisation of the mercury, so that the exact quantity combining with the lead is uncertain. To avoid this, Mr. Walter F. Smith, of Philadelphia, has devised a method by which an amalgam previously prepared is added to the molten lead in definite quantity. The manner in which the amalgam is prepared involves an electrolytic process, and is accomplished as follows: A quantity of mercury is made the cathode of a cell and metallic lead the anode, a dilute solution of nitrate of lead constituting the electrolyte. A current of electricity is then passed through the electrolytic cell and the ensuing electrolysis allowed to continue until the mercury has permeated a large proportion of the lead. The amalgam thus formed is then placed in a straining appliance, and the nitrate of lead removed by washing and the excess of mercury strained off, leaving the mass in a plastic condition suitable for combining with molten lead. In practice it has been found that about four per cent. of the amalgam introduced into the lead before casting the compound into supports gives excellent results and prevents oxidation.

Dry Batteries.—The earliest *dry pile* was devised by De Luc. De Luc's idea was very much improved by the Abbé Zamboni, who thought he had given to the world at last the perpetual motion. Zamboni's pile, as is generally known, consisted of sheets of paper covered with thin laminæ of tin or zinc on one side, and well rubbed with the dioxide of manganese on the other. Later, the discs were formed of "gold" and "silver" paper pasted back to back. The development of the dry battery has made considerable progress during the last few years, attention having been given on the Continent to the subject by Guérin, Edelmann, Pollak, Wagner, and Gassner. The Gassner battery is simply a cylinder of zinc, open at the top, and closed at the base with a non-conducting material; the zinc forms the negative pole. The positive pole consists of a piece of carbon placed within the cylinder. The space between the carbon and the zinc is filled up with a mixture of gypsum and oxide of and the cell is then sealed down with cement. In the Trouvé zinc, pile, soft, bibulous paper is used in discs, thoroughly soaked with solutions of sulphate of copper and sulphate of zinc. Bagration employed earth saturated with sal-ammoniac: Minotto, sand and sulphate of copper; Wolf, Keiser, and Schmidt, sawdust or cellulose. Desruelles, taking the Leclanché cell, endeavoured to make it portable by filling up the space reserved for the sal ammoniac solution with asbestos fibres or spun glass, which soaked up the liquid, Germain used cocoa-nut fibre for the same purpose, D'Arsonval employed animal charcoal. Beetz and Schuler employ sulphate of copper and sulphate of zinc mixed with sulphate of lime or gypsum. Burstyn uses gypsum and chloride of copper mixed with chopped cotton wool. The essential feature of Pollak's dry pile consists in the use of "gelatine-glycerine," mixed with the exciting salts. This substance is admirably hygroscopic; it has been employed by Edelmann in the construction of his pocket battery. Lastly, Raoul Guérin, of Paris, has laid under contribution a new hygroscopic material, for use in dry piles, analogous to gelatine: it is called "la gelosine de Raoul Guérin," and contains a large quantity of the exciting salts.

THE UNDERGROUND MAINS OF THE HASTINGS ELECTRIC LIGHT COMPANY.

BY W. B. SAYERS.

At a time like the present, when many electrical engineers have the difficult task before them of deciding upon a method of laying underground mains, and when not a few new schemes are on the point of being tried, it may be helpful to those whose object is to secure success at any reasonable cost, as distingushed from those who are content to risk present failure in the hope of ultimately attaining a more striking success with a novel system, to consider the conditions under which underground mains have been employed by the Hastings and the Eastbourne Electric Light Companies during the last six years, and the result of the experience of these two companies.

By the courtesy of the secretary, Mr. Ed. W. J. Hennah, and the engineer, Mr. Mercer, of the Hastings Company, the writer has had an opportunity of examining the test books, which contain records of the daily insulation tests back to 1885; and he is thus in a position to give the averages of these tests for the months of June and November up to the present year, and also a general description of the Company's experience as regards underground mains. The Company at present employs the old type Brush dynamos, with cast-iron armature rings. The normal capacity of each machine is 40 arcs of 10 amperes current. By far the greater part of the lighting is by incandescent lamps, which are arranged on the well-known system of groups in series. The mains consist unformly of seven 16 B.W.G. strand cables, insulated either with gutta-percha or indiarubber, and drawn into cast-iron pipes 4in. in diameter, service wires being taken off in 1½in. pipes. There are four independent circuits in all, each worked by a separate dynamo, while one spare dynamo is kept running in case of necessity. The dynamos are mounted on a well-insulated platform, which arrangement relieves the cables of unnecessary strain, especially if the dynamo insulation is not very high. Returning to the mains, No. 1 circuit has a total length of 6½ miles, and operates 30 Brush arc lamps situated along the Marine Parade, outside shops, and in other exposed positions; No. 2 circuit is 3½ miles long, and supplies 300 16 candle-power incandescent and one arc lamps; No. 3 circuit is 3½ miles long, supplies 300 16 candle-power incandescent and one arc lamps; and No. 4 is 6½ miles long, and supplies 400 incandescent lamps, making a total of about 20 miles of cable.

The Company started work in November, 1883, when the mains consisted entirely of cables with thin (less than $\frac{1}{16}$in. gutta-percha insulation with an outside braiding. These cables began to give trouble from the very first, and complete breakdowns of the lighting were constantly recurring. Early in 1884, Mr. Mercer, the Company's engineer, commenced replacing the thin gutta-percha insulated cables with much more heavily-insulated indiarubber covered cables of a type first made specially for Mr. H. M. Sayers, then engineer to the Eastbourne Company. This cable has proved itself equal to the strain of 1,500 to 1,600 volts continuous E.M.F., which it has had to withstand at Hastings. As indicated above, the first length of it was drawn in in 1884, and from that date whenever a fault has occurred in the original gutta-percha cables the faulty length has almost invariably been replaced by the heavily-insulated rubber cable, with the result that at the present time over 10 miles out of the total 20 miles are of this cable. The remaining 10 miles consists of 1½ miles of a thicker gutta-percha cable, which has also proved successful, about six or seven miles of the original thin gutta-percha cable, and between one and two miles of other types. The three principal types of cables in use are as follows: No. 1 is insulated with two coats of gutta-percha, the total thickness of the two coats being slightly less than $\frac{1}{16}$in., then braided. No. 2 is also insulated with two coats gutta-percha, about twice the thickness of No. 1, then braiding of a substantial character. The 1½ miles of this cable has stood well, especially on the pier, where it was put in in 1884, and has never shown a leak or required touching, though in some places the braiding has rotted off completely. No. 3 is by far the most expensive cable, costing about £120 per mile: the sample examined had first a coating of very thin pure rubber wound on spirally to protect the copper from the action of the sulphur in the other coats, then a layer of white vulcanised rubber, and then a layer of equal thickness of grey rubber—the total diameter over the rubber coverings being 0·425in.; next came a serving of prepared tape, and over all three servings of tarred canvas laid on in reverse directions. The outside diameter of the cable is 0·75in. Mr. Mercer says he has never had to replace a single length of this cable, and he consequently uses it with the utmost confidence.

A daily record of the insulation tests has been kept since 1885, and below will be found the average values of the insulation resistances for the four circuits during the months of June and November for each year up to the present, 1889:—

——	No. 1 Circuit.	No. 2 Circuit.	No. 3 Circuit.	No. 4 Circuit.
	Ohms.	Ohms.	Ohms.	Ohms.
June, 1885	105,967	195,322	...	...
Nov., ,, ...	207,533	118,533	...	...
June, 1886	192,800	107,500	...	...
Nov., ,, ...	120,133	253,800	189,666	...
June, 1887	575,333	283,600	231,633	...
Nov., ,.	74,366	299,833	181,700	...
June, 1888	258,100	141,900	115,800	...
Nov., ...	91,633	122,566	88,933	...
June, 1889	242,266	154,333	103,133	92,166
Nov., ,, ...	147,700	223,500	260,000	193,000

The figures represent the insulation of switches, fuses, lamps, &c., and if all these were disconnected, and the cables joined up, obviously a much higher result would be obtained. An examination of the test-record shows that 12,000 ohms is the lowest insulation resistance which any circuit has shown without a fault having been the cause; while in August, 1888, a resistance of only 7,000 ohms was given by circuit No. 3, when a fault was localised and removed. At the same time cable faults of as high a resistance as 100,000 ohms have been localised and removed. Nothing but practice and experience in the observance of the behaviour of machines and lamps, as well as the behaviour of the instruments when the test is being taken, and the state of the weather can enable any one to judge with accuracy whether a fault exists in the circuit, or whether a low reading, or succession of low readings, is caused by surface leakage at switches, fuses, or lamps, or in the case of arc lamps, even over the surface of damp globes. Given the required experience and observance on the part of the engineer in charge, and a cable fault of 100,000 ohms resistance and upwards gives sufficient evidence of its existence to enable it to be traced and removed. At Hastings faults are now of very rare occurrence. The last one which caused a stoppage of lights was in December, 1887, when a short-circuit occurred in No. 2 circuit close to the station. The most recent leaks which have been remedied occurred in August, 1888, on No. 3 circuit, and in October, 1888, on No. 1 circuit. These were both traced to the No. 1 quality cable—that is, the first put in. An examination of the actual "faults" removed shows them to be due invariably to one of two causes, viz., defects in manufacture, which have gradually developed "pinholes" under the action of the leakage current—infinitesimal at first, but none the less surely operative; and mechanical injuries, received either in transit, whilst being drawn in, by being sawn into by other cables drawn into the same pipes, or by too sharp bends over corners of projections, or from kinks.

Mr. Wilkinson, of the Eastbourne Company, states that the underground mains employed by that Company, which consist of similar indiarubber cables drawn into iron pipes in a similar manner, have given no trouble with the 2,000 volts alternating E.M.F. to which they are subjected.

The experience of these two Companies points to but one conclusion, which is, that even a thin coating of either rubber or gutta-percha, if the coating is only perfect from end to end, is sufficient to withstand 1,600 to 2,000 volts, either direct or alternate. The process which has been going on at Hastings has simply been the weeding out of the lengths of cable which contained either mechanical injuries or defects which occurred

Digitized by Google

during manufacture, and this process has now been carried on to such an extent that even the 6½ miles of the original thin gutta-percha covered cable which remains in use seems capable of standing the work indefinitely. The advisability of subjecting all cables to a severe and prolonged test under a high potential has often been urged, and in the light of the results of experience at Hastings and Eastbourne, certainly no pressure of circumstances should ever be allowed to interfere with the thorough testing and proving by means of a high E.M.F. applied for several days at least to every length, and the rejection of every unsatisfactory length unless the weak point can be localised and cut out. But there is another point of no less importance, and that is the handling of the cable when it has withstood the test. Too much care and thought cannot be exercised when making the arrangements for drawing into the pipes or conduits. In the summer of 1883 the writer was engaged in connection with the lighting of the Birmingham Town Hall for the occasion of the Musical Festival of that year. The dynamos were driven by the mill engine in a well-known sheet metal and tube works in Cambridge-street, a distance of about 500 yards from the Town Hall. Underground mains were decided upon, and a double set of eleven 7-16 B.W.G. strand cables were employed: twenty-two cables in all. Four-inch pipes were procured from the water company and the more prominent projections on the inside of the pipes removed or rounded off by dragging several lengths of a heavy chain backwards and forwards through each pipe for about 15 minutes. The testing, drawing in, and jointing of the cables were arranged and supervised by Mr. Fleetwood, of the Post Office, who took the greatest precautions against mechanical damage. Each eleven 110 yard lengths of cable were laid together and wound from end to end with canvas strip, a brass trumpet-mouth funnel was put into the end of the pipe at which the bunch of cables entered, and two or three pounds of soft soap put into the mouth of pipe and over the ends of the cable to lubricate the surface and make all go smoothly. For several years no faults whatever occurred in these cables, and they are still in satisfactory order, lighting the Town Hall, the Birmingham and Midland Institute, and one or two other adjacent buildings. The E.M.F. employed is 240 volts, and the cables are insulated with gutta-percha about 0·075in. thick, braided over all. What can be more manifestly absurd than to pay a high price for a cable and to exact guarantees from the maker that the insulation resistance is so many megohms per mile, to spend a great deal of time and trouble in testing and proving the manufacturer's work, and then to hand it over to unskilled labourers and inexperienced pupils to uncoil it and entangle and kink it, to re-coil it and uncoil it again, and finally to drag it by main force into the pipes, without any efficient precautions against abrasion or damage from overstraining, should any hitch or kink occur at the ingoing end? Yet this is the kind of treatment to which underground electric light cables have been, and doubtless are being, subjected in many instances. No surprise need be felt if the insulation of such cables failed to stand the test of regular work.

SIR WILLIAM THOMSON'S NEW INSPECTIONAL ELECTRIC INSTRUMENTS.

The following instruments of Sir William Thomson have not, we think, been hitherto fully described:—

The Magneto-static Current Meter.

The Magneto-static Current Meter consists essentially of a small steel magnet or system of magnets suspended in the centre of a uniform field of force due to two coils, each having one or more turns of copper ribbon or wire, and also under the directive influence of two systems of powerful steel magnets. The suspended system of magnets is attached to one end of a vertical shaft passing down centrally through an opening in the sole-plate of the instrument from an indicating needle. The two systems of directive magnets are circular in form, and each ring is composed of two semi-circular magnets placed in a brass cylindrical frame with their similar poles together. Each system is securely fixed to a circular brass frame, which fits on to the cylindrical case of the instrument in such a manner that the systems are capable of being turned round, together or separately. The instrument has a "tangent scale," consisting of a hundred divisions, which is adjusted in its position before the instrument is sent out, so that the needle indicates equal differences of readings for equal differences of current.

The instrument has an advantage, important for some practical purposes, of being available as an accurate direct-reading current meter, through a continuous range of from 1 to 100 times its smallest current, which may be anything from half a milliampere to four amperes, according to the number of turns in the coils supplied with the instrument. It is not, however, available as an alternate-current instrument, and it must be remembered that the magnetism of the steel directing-magnet does not remain *absolutely* constant. With good quality of steel, a proper preliminary *ageing* of the magnet (by heating it several times in boiling water and cooling it again, and subjecting it to somewhat varied rough usage) brings it to a condition in which its magnetism is found to remain exceedingly nearly constant month after month and year after year. Still it should never be relied upon as *absolutely* constant, and for accurate laboratory work it is therefore necessary to have some means of re-testing the instrument at any time. Another advantage which the instrument has is that, when a standard instrument is available, its constant is capable of being varied to any desired value down to one-tenth of that which it has with its directive magnets in their strongest position. Thus if the constant should be three amperes per division of the scale, with the similar poles of the magnets coinciding, it may be adjusted to any value down to 0·3 ampere per division.

The two grades of this instrument which are found most convenient are:—The Milliamperemeter, which has an effective range of from ·3 to 300 milliamperes, and is usually adjusted to read two milliamperes per division, and the Amperemeter, which has an effective range of from ·3 to 300 amperes, and is usually adjusted to read one ampere per division.

One very convenient use of the latter instrument is to act as a lamp-counter for indicating the number of incandescent lamps in use in an installation. For this purpose it is best to standardise it by putting on a known number of lamps and adjusting by the magnets until the desired reading is obtained on the scale. Of course this numbering of lamps is not possible to any great accuracy, because the lamps themselves are not all rigorously equal in the amount of current which each takes, but the lamp-counter serves the important practical purpose of showing at any time the number of lamps in use nearly enough for practical purposes. The Milliamperemeter, on account of the low resistance of its copper coil—about 40 ohms—may conveniently be used as a voltmeter. To adapt it for this purpose a copper cylinder, wound anti-inductively with two platinoid resistances, is supplied. The first of these, together with the resistance of the instrument, makes up 100 ohms, and the second alone is 900 ohms. Thus, taking the constant of the instrument at 2 milliamperes per division, by joining the smaller in series with the instrument, the reading on the scale will be 1/5 of a volt per division; with both resistances in series with the instrument the reading will be 2 volts per division.

The Ampere Gauge.

The Ampere Gauge (see Figure) is of simple construction, having a vertical base-plate of paraffined marble, to which are attached:—(*a*) A solenoid of special form; (*b*) Brass bearing plates supporting a balance which carries a soft iron plunger on its one arm and a brass counterpoise weight on the other; (*c*) A brass arc having a scale graduated to give direct readings in amperes; (*d*) A hinged arm which bears a light checker. The solenoid is built up of copper plates with mica insulation between them, and is fixed to the base-plate so that its core is vertical. The balance is supported on knife edges at such a distance below the solenoid that the top end of the plunger is slightly entered into the core. The plunger is made from a thin soft iron wire about 20 centimetres long, and is supported by a cross-bar with two hooks on it which pass over two knife-edge stirrups on the arm of the balance. It has a brass weight hung on its lower end in order

Digitized by Google

to keep it in a vertical position and prevent its being attracted against the side of the solenoid. An indicating needle, or pointer, formed from a strip of platinoid, passes down from the trunnion of the balance to the brass arc bearing the graduated scale. As the plunger is attracted upwards this pointer passes round the scale and indicates the strength of current passing through the solenoid.

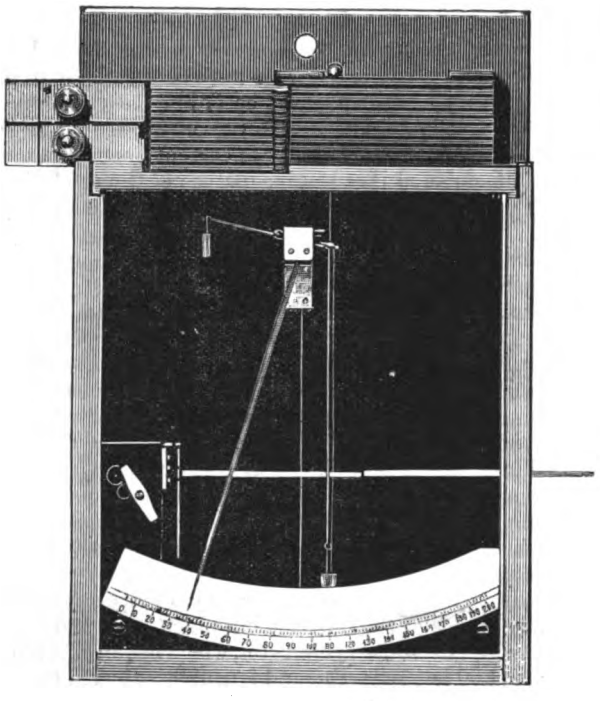

Fig. 1.—The Ampere Gauge.

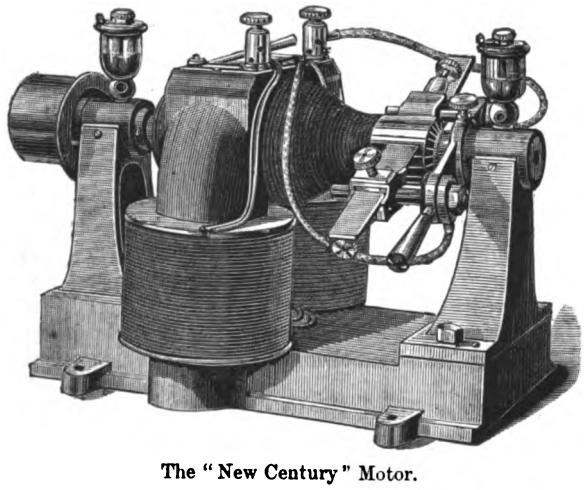
Several types of the Ampere Gauge are made, covering a range from 0·5 to 500 amperes, and are available as measurers of electric current on either direct or alternating circuits. They are standardised by direct comparison with Sir William Thomson's Standard Electric Balances, and, when the instrument is intended for alternating currents, the graduation is made to suit the period of alternation in use on the circuit for which it is desired.

THE "NEW CENTURY" ELECTRIC MOTOR.

Among the numerous American Companies who propose to "open up" business in England is the New Century Dynamo



The "New Century" Motor.

Company. This Company makes a special feature of its motors, one of which is illustrated in the accompanying engraving. It is of the inverted horse-shoe type. The distinguishing feature of the machine is the construction of the magnetic circuit, the magnetic cores, pole-pieces, the yoke and base, together with one of the bearings, being all cast in one piece; the absence of joints considerably reducing the resistance of the magnetic circuit. The armature is of the Siemens-drum type. The field-magnet coils are separately-wound on pasteboard tubes with fibre flanges, the whole being then slipped over the magnet cores. The shaft which carries the armature is made of high-grade steel turned exactly to gauge, and all other parts are made interchangeable. The commutator is made of Tobin bronze, an excellent wearing metal, and is insulated with mica and carefully backed. The motors are shunt-wound and have a three-point starting switch on top of the machine, which obviates the use of a separate resistance box. The first contact on this switch throws the field in circuit, thus magnetising the cores and permitting the motor to start itself. The second contact puts in the armature and also a resistance in series with it to prevent the armature from burning out when starting. The last contact short-circuits this resistance after the motor has obtained its proper speed, and it then acts as a simple shunt-wound motor, keeping its speed practically constant, there being but a slight variation between full load and no load.

The New Century Company also manufactures a large number of electro-plating machines.

THE ACTINO-ELECTRIC RESEARCHES OF M. STOLETOW.*

The phenomenon studied by Stoletow and discovered by Hertz, namely, the discharge of electricity by light, has been the object of numerous works by Wiedemann, Hébert, Righi, and others. Stoletow has, however, devised a particular method which gives his investigations an entirely original character, and which has given rise to some interesting results.

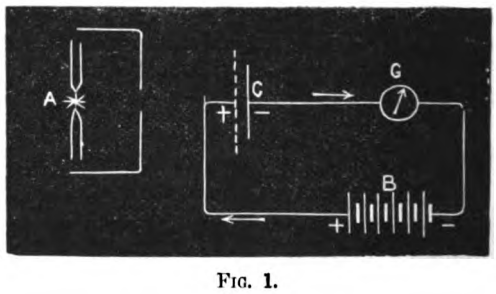


Fig. 1.

In Fig. 1 we have a diagrammatical representation of his method. A is a Dubosq arc lamp with the lenses taken away, run off a dynamo giving 70 volts and 12 amperes. A condenser consisting of two metallic discs, ·22mm. in diameter, is arranged in front of the opening of the lamp. These discs are not similar, the one nearest the lamp consisting of iron or brass network, the other is a plate of the ordinary description. These two discs are arranged in a vertical plane, are parallel, and the distance between them can be altered as desired. The light passing through the network strikes the near coating of the plate, which thus becomes the seat of actino-electric phenomena. The two coatings of the condenser C are connected by a metallic circuit containing a battery, B, a sensitive Thomson galvanometer, G, which deflects one division for every $2{\cdot}7 \times 10^{-11}$ amperes, or one division for $6{\cdot}7 \times 10^{-10}$ amperes when the controlling magnet is taken away.

With the apparatus so arranged M. Stoletow obtained the following results:—When the plate was connected to the negative pole and the network to the positive, there was a current in the condenser circuit each time that the light of the arc fell upon the negative plate. If the connections were reversed the actino-electric current was scarcely perceptible. If it were not completely stopped, it was because the negative pole (the network) was still lighted up by reflected light; but if the sensitiveness of the network were diminished (we shall see further on that to attain this result it was only necessary to slightly wet it) the current completely disappeared, so that Stoletow agrees with previous observers in asserting that the actino-electric current is unipolar. The voltaic arc was not the only cause of these phenomena: gas flames, magnesium light, induction sparks, gave rise to the same effects,

* From *La Lumière Electrique.*

Digitized by Google

though in a feeble manner. Sun rays seemed to have no action at all. M. Stoletow has exposed his condenser at right angles to the sun's rays, and although the plates of the condenser were only 1mm. apart and its potential was 212 volts, there was no current. Under the same conditions, when the condenser was exposed to the light of the voltaic arc, there was a current of $640 \times 6{\cdot}7 \times 10^{-10}$ amperes. The introductinion to the voltaic arc of metallic vapours, especially those of aluminium, considerably increased the actino-electric effects, and, generally speaking, all gases which increased the number of rays of great refrangibility in the arc also increased the actino-electric action. On the other hand, all substances, opaque or transparent, which absorbed these rays when interposed between the light and the condenser, immediately stopped the actino-electric current. Such was the effect of glass. Water, quartz, ice, are more or less transparent to the ultra-violet rays, and are consequently to a certain extent transparent with regard to actino-electric action. Amongst the gases air and hydrogen are transparent, but coal gas, ammonia, and the vapours of sulphate of carbon are nearly completely opaque. An interesting peculiarity ought perhaps to be mentioned here. If the surface of the negative plate which received the action of the light was covered with an extremely thin coating of some transparent material, the actino-electric action was rapidly reduced to nothing. Hence the actino-electric current instantly ceased if a little water was poured on the negative plate, or even if it was breathed upon. On the other hand, if the negative surface was covered with a material which absorbed the active rays, it became more sensitive ; hence colouring substances double and treble the actino-electric sensitiveness of the condenser. These effects indicate the part played by the violet rays in the production of the phenomenon, and show at the same time that the *surface* of the negative plate plays the most important part. The experiments of Lenard and Wolf on the pulverisation of the negative surface by light leave, moreover, no doubt on this point. The different metals have not any marked specific sensitivity, but the study of their surface may considerably alter the constant. Thus freshly-cleaned metals are the most sensitive, but they become quickly "fatigued," so that if constancy is required freshly-cleaned metals should *not* be employed. The temperature seemed to have but little effect, but, generally speaking, increase of temperature increased the sensitiveness of the apparatus. This variation in the sensitiveness of the metallic surface rendered accurate measurements very difficult ; but the arc, with its inevitable unsteadiness, was a still greater cause of inaccuracy. The best of arc lamps are not absolutely steady, and the fluctuations of the current due to the irregular action of the machine resulted in a very visible oscillation of the arc. For this reason, M. Stoletow devised a second condenser to neutralise the effect of these oscillations.

This second "controlling condenser" only differed from the first in the shape of its plates, which consisted of two parallel metallic crosses 22cm. long and 2cm. broad, placed 2mm. apart. This condenser was arranged parallel to the first and nearer the arc, so that the same light fell upon it. The controlling condenser was charged by 25 Clark cells, and its circuit contained a galvanometer, the needle of which oscillated isochronously with that of the main circuit galvanometer. The observations were taken simultaneously by two people. At the commencement of each series of experiments (which did not last long, since the two condensers became unequally fatigued), the coefficient of comparison between the indications of the galvanometers was established. The figures given by M. Stoletow show a pretty satisfactory agreement between observations and results calculated by means of the coefficient of comparison. The employment of a controlling condenser led M. Stoletow to study the influence of the intensity of light, of the surface of the electrode, and of time upon the strength of the electric current. By means of a cardboard disc cut into equal sectors, and revolving at a known speed, it was found that the intensity of the actino-electric current was proportional to the active rays (ultra-violet). If a certain portion of the negative disc was covered with transparent substances, which annulled the action of the light, it was found that the current was proportional to the surface. Finally, a commutator, fixed upon the axis of rotation of the cardboard disc, permitted one to introduce or take out from the circuit the actino-electric current for a certain portion of the angle of rotation—that is to say, during an extremely short time. By these means it was ascertained that the action of the light is practically instantaneous, the retardation being less than one-thousandth of a second. This conclusion is contrary to the view of M. Borgmann, another Russian scientist who has devoted himself to this question, and who employed a telephonic method ; but it seems that the experiments of M. Borgmann can be interpreted in another manner.

With his controlling condenser M. Stoletow carried out a series of measurements with a view of studying the actino-electric current as a function of the distance between the plates of the condenser, and of its potential. The plates of the condenser which was employed in these investigations were of silvered brass. The negative plate always occupied the same position, and the network alone was displaced. The distance between the plates in these experiments was varied from X+1 to X+95mm. (X=1·5mm.). The E.M.F. of the battery varied in one series of experiments from 1·4 volts to 140 volts ; in another series between 1 Daniell and ·05 Daniell. The results of these experiments are shown in Fig. 2. The greater the distance (δ) the further off from the point of origin is the bend of the curve. Comparing the curves, M. Stoletow first showed that C is a function of $\frac{E}{\delta}$, which he verified directly by varying E and δ at the same time in the same ratio. Hence, as $\frac{E}{\delta}$ (δ being small) is a measure of the density of the charge, or the electric forces at the surface of the plates, and in the medium which separated them, M. Stoletow concluded that the intensity of the actino-electric current is a function of this density [$C=f(\sigma)$], so that, making $\delta=1$, we shall have $C=\phi(E)$, the curve of which is analogous to the curves resulting from the experiments. This curve shows that C for small E.M.F.'s increases rapidly with σ, but when E becomes large, C seems to tend to a saturation limit.

To make sure that $\frac{E}{\delta}$ was a measure of the E.M.F.s between the plates during the passage of the actino-electric current, M. Stoletow investigated by means of the electrostatic method the fall of potential at this moment, and ascertained that this fall is always a linear function of the distance $\left[V=V_0+(V_1-V^0)\frac{x}{\delta}\right]$. The same method showed that the difference of potential between the plates did not change under the influence of light, so that owing to the enormous resistance $\left(\frac{E}{\delta C}\right)$ of the layer of air the discharge produced by the light was rapidly restored by the battery.

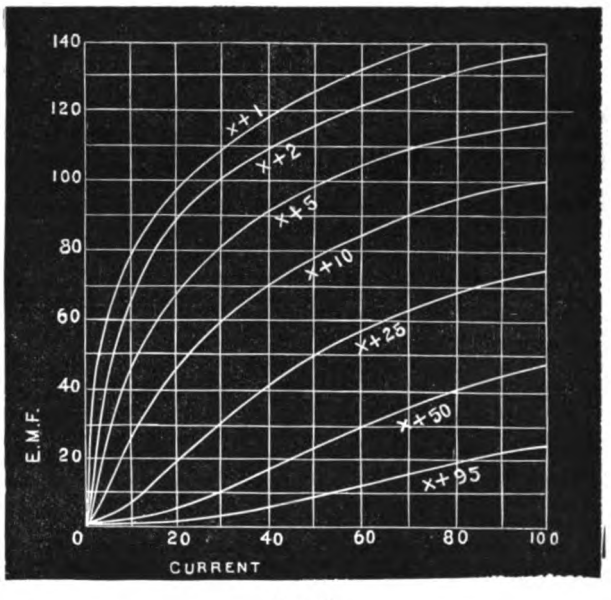

FIG. 2

The difference of potential of the plates is equal to the E.M.F. of the battery where the two metals are identical ; but if they are different it is necessary to add the E.M.F. of contact. The question then arises, does this E.M.F. take any part in actino-electric phenomena ? The apparatus was sensitive to ·01 of a Daniell, and M. Stoletow completely eliminated the battery from the circuit and charged his condenser merely by contact force. The experiment was completely successful, using silver as the negative plate, zinc as the positive plate. The system of zinc, air, and silver lit by the electric light thus became a veritable battery, in which the E.M.F. was furnished direct by the intensity of the light. M. Stoletow also measured the E.M.F. of Zn/Ag by the actino-electric current, and obtained a figure approximating very closely to those obtained by Pellat, Kohlrausch, and others. It would seem, therefore, that we have here a new galvanometric method of measuring this important constant.

Wishing to vary his experiments as much as possible, M. Stoletow effected his measurements by a method which consisted in charging a condenser of great capacity, and measuring the discharge current. Applying this method to the case in which his condenser was only charged by contact potential, M. Stoletow found that if the action of the light lasted longer than was necessary to discharge the negative electrode, the discharge current was stronger

Digitized by Google

than it ought to be. Hence it appears that the light not only discharges the electrode, but gives it a positive charge.

M. Stoletow does not give a theory concerning these phenomena, but, in his opinion, there is a great analogy between them and those of the discharge of gases in Geissler tubes. To him a condenser of this kind is nothing more than a Geissler tube, worked by an external source of light in a non-rarefied atmosphere.

ELECTRIC WELDING.*

BY C. E. HARTHAN.

During the present century only iron and steel, or possibly bronze, were considered weldable, and quite recently platinum. When we studied physics, we were taught that the weldable class of metals were iron, steel, and platinum, all others being unweldable, but now we can weld almost every metal known, and perhaps every metal. I know that every metal tried by the Thomson electric welding process has been welded satisfactorily. Prof. Thomson may therefore be credited with having introduced a universal method of welding. While he was preparing a lecture on physics before the Franklin Institute at Philadelphia, about twelve years ago, he made an experiment to illustrate the reversibility of an induction coil. The discharge of a Leyden jar and a Rhumkorff coil were used. While working with it, it occurred to him that it would be a very pretty experiment to reverse the process. This was done, and he was much astonished at the volume of current obtained: the ends of the primary were brought into contact and actually stuck firmly together. The experiment was repeated several times. The recent experiments of welding by electricity are the outgrowth.

When the Thomson-Houston Company and other electric companies commenced to manufacture dynamos, they could not get copper wire in lengths long enough to wind the armature with; the soldered joint was an objection, as it took time to make; the soldering acid would soak through the insulation and cause a short-circuit, and the result was a burned-out armature; and the loss of short pieces of heavy copper wire was considerable. The first welding apparatus worked very successfully, and welds made with it were put to practical use in the factory of the Thomson-Houston Company, such work as welding copper, iron and steel wire, joining short pieces of heavy copper wire, to be used in the series coil of the incandescent dynamo, welding Stubb's steel shanks to drills, taps, reamers, &c., welding band saws for pattern shop, lengthening bits for expert's use, lengthening brass rods, &c.

The Thomson process of electric welding, which might be called the incandescent method as contrasted with what is known as the arc method of electric welding, was first brought before the public at an illustrated lecture given by the president of this club before the Society of Arts, Boston, in December, 1886, where it was shown in working order with a lot of specimens. The process of arc fusing might be mentioned under the head of electric welding. In this process the direct current is used of sufficient potential to maintain an electric arc. The pieces to be joined are made one electrode and a piece of carbon or some suitable material is made the other. The carbon piece is first brought in contact with the pieces to be welded, then separated after the current has been turned on; by so doing the arc is obtained, then move along or about the joint to be made. The effect of the arc (the heat of which is very intense) is to melt the metal, but iron and steel and other metals are burned to a certain extent. I have seen some of the specimens, but did not call them at all satisfactory. They appeared to be very spongy, and small holes in them in some portions, shown to have been burned or very much overheated. They had no strength—seemed like rotten iron. The heat is applied in the wrong place, the current having been directly across the junction instead of through it as in the Thomson method. Serious difficulties are met with in keeping the arc the right length and fed along properly, which is done by hand. It is very trying to the eyes even when protected. Another difficulty is the regulation of the dynamo, although the storage battery is used.

In the construction of a welding coil care must be taken that there are no other circuits made elsewhere than in the welding circuit. There must also be about as much section of copper in secondary as total section of primary, or, in other words, the same number of ampere-turns in each. The joints in the welding circuits should be as few as possible, and what joints are made must be perfect in contact, as a poor contact means immense loss of energy by unnecessary resistance, as we are dealing with very low potential—about one or two volts—and very heavy currents. The core is made of laminated sheet iron discs bolted together, with hole in centre large enough for secondary and primary circuits. The primary consists of coils wound on a form and slipped on to the core through an opening which is afterwards filled with laminated phig. The secondary is often a heavy copper tube or bar passed through the centre of core, connected at the two ends with copper castings, connecting with welding clamps, and in such case the joint at the end is made on a taper set up tight to ensure contact with a nut, thread having been cut on end of copper bar. This whole is placed on a proper base, with a sort of table at the top which supports the clamps and pressure device. The clamps are usually made with one clamp kept stationary during welding and one movable clamp, the pressure power being obtained by a screw worked with a worm wheel or rachet.

The welding dynamos are all similar in form, but vary in size and connections. The form is of frame, with field-magnets projecting inward, having four and six field-poles made of separate plates of iron securely bolted together and to frame, the coils being slipped on in the ordinary way. The bearings are made self-oiling. The armature is a type of its own: it is a pole armature—that is, the core has four or six projections; the coils are wound on these. It cannot be called a drum armature, nor Pacinotti, nor Siemens, but perhaps a modification of the shuttle type. Perhaps the name multipolar Siemens shuttle might be suggested. The alternating current is taken off the collector rings in the ordinary way. The dynamos are divided into different classes—the two, four, and six-pole machine, also self-exciters, separate exciters (where fields are excited by small dynamos), and composite dynamo. They are generally wound for 300 volts, and run at a rate of 100 alternations per second, or 6,000 per minute. The four-pole machines are run at a speed of 1,500, the six-pole 1,000 per minute. As the dynamo is doing work only at short periods and not constantly, the output is much more than it otherwise would be for the same size of machine for continuous work. They are of much less weight for the same number of watts than an alternating lighting generator.

Some of the first questions asked by a person who has seen the welding for the first time are:—"How much power does it take? How strong are the welds? Can you weld all metals? How large can you weld?" &c., &c. Horse-power required is an important factor in some cases, or where power is limited; but in cases where joints cannot be made by any other process, power is not so much a question, or where power is in abundance and easy of access, such as water power. Here a difficult task was met with. Instruments are not made to measure such heavy currents; even if they were, they could not be introduced in the welding circuit or secondary conductor of the welder, as it is so very short—only a few inches long. So instruments had to be constructed for the purpose, and the horse-power has been measured in more ways than one. Something over a year ago a series of power tests were made by means of the calorimeter. The result of tests made this way show that the average power consumed in a ½in. bar of iron welded is about 6½ horse-power, welded in 10 seconds; 1in. round iron, 12 horse-power, welded in 40 seconds; 1½in. round iron, 18 horse-power, welded in 90 seconds. Probably these results are not absolutely correct, as they were obtained from a very crude apparatus, but I think they are within 10 per cent. Comparison of different results shows that from 65 to 72 per cent. of the total energy of the engine is consumed in the weld.

The time taken in making a weld is a very important factor, as the quicker the weld is made the more power is consumed for the time. If a piece of 1in. round iron is welded in 40 seconds, and requires 20 horse-power, it would require about twice the power to do the same work in one-half the time, or about one-half the power in twice the time. This theory holds good within a wide range, perhaps 30 or 40 per cent each way from the table just given. If a weld is made too quickly, the metal is burned at the ends in contact; if made too slowly, the machine and clamps are over-heated, and energy is lost by radiation of heat.

The distance between the clamps is another factor; the less projection of the piece beyond the clamps the less power is used, as the resistance through the bar is lessened, but, as the pieces become heated to high temperature, the clamps absorb the heat, and are also burned if too close. If too great projection is given much power may be lost from radiation. and a longer length of bar will be heated than is necessary. For heavy work, and that done continuously, it is found necessary to employ a method, already worked out in early welding patents, to keep the clamps cool: this is done by having them constructed with water circulating round them. The fact that the resistance increases as the temperature increases is a great benefit in welding, as the bar heats at the ends in contact on account of the high resistance, also heats more at heated portions on account of increasing resistance, thereby localising the heated portion of the bar during the welding operation. By continued experiment the best results, everything taken into account, are when the projection beyond each clamp is a certain relation to the diameter of the stock—that is, for round bars of iron.

It is often asked how much current does it take to weld a bar of iron, &c.? This depends on the time in which it is done, &c. As the potential is very low, only one or two volts, the amperes are

* Lecture before the Thomson Scientific Club, Lynn, Mass.

Digitized by Google

reckoned in the thousands. For a 1in. round iron about 5,000 amperes in 40 seconds; for a 2in. round iron about 20,000 amperes in 80 seconds.

This electric welding process has become so universally known that the general public expect almost too much from it. It surely is a great invention and a very important one, but still there is much work of development for special cases to be done; and as to size of piece, the limit may be reached some time, but it has not as yet been reached. It is expected by some people that everything can be welded by the electric current. That is expecting too much, but nearly every kind of metal can be welded. Among the metals that have been welded are: gold, platinum, silver, copper, aluminum, bismuth, cobalt, antimony, zinc, tin, lead, iron, nickel, magnesium and manganese. Among the alloys welded are: the different kinds of brass and bronze, phosphor bronze, aluminum bronze, silicon bronze, numerous grades of steel, cast iron, malleable cast iron, German silver, lead alloys, tin and lead, and others. Among the combinations of different metals are: copper to brass, brass to iron or steel, brass to German silver, German silver to iron or steel, nickel to iron, iron to steel, cast iron to wrought iron, German silver to copper, lead to tin, tin to zinc, brass to tin, gold to silver, gold to platinum, silver to platinum. Prof. Thomson has a welded bar three-eighths of an inch in diameter made of different metals, nine pieces. It is made up in the following order: copper, brass, iron, German silver, brass, tin, zinc, tin and lead. A similar bar was sent to the Paris Exhibition.

As to the strength of these welded bars, an inspection of the report of tests made on the Rich testing machine, the property of the Company, at their factory, shows that wrought iron may be welded to stand the same tensile strength as the unwelded bar. When a perfect weld is made the fracture is usually within the heated portion of the bar, caused by the stock being annealed at that section. If a welded bar breaks at the weld it is no sign the weld was a poor one, so long as the tensile strength is up to the standard. If the weld by the ordinary blacksmith process stands 70 per cent. or 75 per cent. of original stock it is called excellent. We are not satisfied unless as high as 85 per cent. is reached with the burr removed. Hammering the weld lightly at the welding heat gives it more strength; 95 per cent. and even 100 per cent. is then reached, and, of course, if the piece break some way from the weld the joint is much more than 100 per cent. Wrought-iron bar stands about 50,000lb. per square inch. Norway iron bar stands about 60,000lb. per square inch. Mild steel may be welded without difficulty. Tool steel is also welded without much trouble. Tool steel welds are not as strong usually as the unwelded bar, although the percentage is pretty high, the average being from 80 per cent. to 85 per cent. of annealed stock. Yet these joints are vastly stronger than the same area of wrought iron. Tensile strength of mild steel is from 60,000 to 80,000lb. per square inch. Tensile strength of tool steel is from 75,000 to 120,000lb. per square inch, and even higher. The strength of a tool steel weld is greatly improved by light hammering while at the welding heat if properly done. The welding heat of steel is far below that of iron, so, therefore, in welding steel, more pressure is required than with iron to effect the weld, because the steel is not so plastic and soft as iron while hot. The limit between the burning point and non-welding point is very small, so it is an easy matter not to effect a good weld. But after a little practice, with care it is welded without difficulty. The higher grades of cast steel require as much real care to effect a good weld as anything dealt with. The heat produced by the current of electricity is not materially different from the heat of a forge, fire, or gas flame, but it is developed in the bar from the inside, not outside. Iron will weld if pressure is applied and sufficiently high temperature is reached, it matters not how heated, whether by electricity or otherwise, but we get the avoidance of dirt and impurities. We also get the avoidance of irregular heat in the two pieces. Also by this method only a limited mass is heated. It is not known if the current has any effect in assisting the union in addition to its heating effect. Iron and steel are welded together readily and with very good results in regard to tensile strength, the fracture usually occurring in the iron. Copper is welded very readily, and with substantially the same strength as original annealed stock. Copper is annealed at the section of the weld, but is easily toughened by rolling or drawing. Tensile tests of welded copper show 90 to 98 per cent. of annealed stock. The conductivity of welded copper shows 100 per cent. as compared with unwelded copper: this can also be said of phosphor bronze and silicon bronze, as used in the electric railway. The tensile strength of annealed copper is about 32,000lb. per square inch. Wrought brass is welded without difficulty. The percentage of tensile strength is very high. The tensile strength of annealed brass is about 47,000lb. per square inch. Very good joints are made between brass and iron. The fracture is usually of an irregular nature, sometimes in the brass, but usually at the weld. Iron and steel chains are welded with very good results. Chains are usually made (by this process) with a double weld in each link, or a weld at each side. Chains have been welded and tested in sizes from $\frac{1}{16}$ wire to 1in. round iron. Chains made from $\frac{1}{16}$ wire stand a strain of 260lb. Chains made from bar of $\frac{1}{16}$ iron stand a strain of 130lb., or 40,600 lb. per square inch. This chain stood 200 per cent. of a single wire of same material annealed. A chain of $\frac{1}{8}$ wire stands a strain of 1,180lb. A chain of $\frac{1}{8}$ iron bar stands a strain of 790lb., or 61,500lb. per square inch. This chain stood 150 per cent. of a single wire of same material. A chain of $\frac{1}{2}$in. round steel stands a tensile strength of 22,000lb. A bar of 1in. round steel stands a tensile strength of 15,000lb. This chain stood 147 per cent of single bar of same material. A chain of 1in. round iron stands tensile strength of 65,400lb. A bar of 1in. round iron stands tensile strength of 38,000lb. This chain stood 172 per cent. of a single bar of same material. The reasons why a chain does not stand twice the tensile strength of one solid bar of same material are several. There is a shearing strain at the end of link, also a bending strain, as the link is lengthened by pulling. The fracture is usually at the end of the link, or just one side, between the weld and the end of the link.

The variety of uses to which this method applies is unlimited and too numerous to mention to-night; but now that I have given an idea of what the Welding Company has done and is doing at the present time, it may, perhaps, be of interest to say something as to what they may do at some future time. Probably there is no invention which covers such a broad field of work with such a variety and kinds of work. The business of constructing and supplying the necessary appliances must grow to be very large. It will not be confined to the United States, but will be open to foreign countries in all parts of the world. It is now represented in the United States, Canada, England, Scotland, Belgium, and France. It would be useless to try to name the various uses this could be applied to, but a brief and incomplete statement of some of the uses might convey some idea in a small way: Rod and bar welding up to 6in. or 10in., or more; joining bars of different shape and section; welding and laying sections of railroad track; welding and putting up conductors for electrical purposes; making joints at angles with bars as T or Y joints; pipe work, welding, brazing, soldering, elbows; T joints, &c., for non-leaking pipes, such as natural gas or oil pipe lines, boiler tubes, &c.; working, joining, &c., of lead pipe, chain and link work, from smallest jeweller's work to heavy "2" iron ship cable, or more. Much of these kinds of work will probably be accomplished by automatic machines. Endless rings, hoops, and tires, from finger rings of precious metals to heaviest iron or steel bands imaginable; tool construction in great many forms, from steel points on mathematical instruments of German silver, &c., to steel edges of heavy cutting tools; construction and building of machinery, such as constructing parts of firearms, dentist tools, carriage and waggon work, locomotive frames, ship machinery, &c.; shaping in great variety of ways by revolving pieces kept hot by electric current; boiler work, riveting, brazing, soldering, &c.; bridge work, riveting, brazing, and forming; ornamental iron work, such as fences, &c. In the heavy machines of the future the construction will be mechanically different, an attempt being made to get better and better efficiencies from the coil. It will be desirable for heavy work to construct hydraulic pressure devices and hydraulic clamping devices, with cooling devices; also cranes for handling such work. Where hammering is beneficial, an electric hammer to operate by means of electric current has been planned. But the details of the future cannot be dealt with, so we will close, and trust the Welding Company may successfully meet the demands of future growth and prosperity.

Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, 1, *Salisbury-court, Fleet-street, London, E.C.*

THE ART OF INSULATION.

To protect an electric conductor efficiently, so that under no circumstances electricity shall escape from it by an undesired route, is an art not to be acquired without both knowledge and experience. Knowledge of the laws and properties of electricity, experience in their application to the circumstances of the case, and, as a *tertium quid*, sound conscientious workmanship in execution—these three go to the art of insulation. Nor must a certain amount of mechanical engineering be forgotten, since efficient insulation depends in almost every case upon the selection of materials which shall be both mechanically and electrically adapted for the purpose which they are to serve.

Since the days when STEPHEN GRAY made the momentous discovery that an electric discharge, though it could pass along a metallic wire or a damp hempen thread, would not flow along a silken cord, it has been customary to classify materials into two classes, conductors and non-conductors. No one, however, has been able quite to say at what point the one class ended and the other began, since they merge into each other. But in view of the fact that some of the so-called non-conductors do not become appreciably conductive, even under extremely great electric pressures, these excessively resisting substances have been used for the purpose of protecting electric conductors from leakage, and so have become known as insulators. Some writers have classified insulating materials under three classes—the stony and vitreous bodies, such as porcelain, glass, mica, and asbestos; the resinous, gummy, and fatty bodies, such as shellac, gutta-percha, indiarubber, ozokerit, wax, paraffin, and the oils generally; and lastly, gaseous bodies, such as the air. The brown stoneware insulators which support our telegraph wires are as familiar objects to the British citizen as the blue glass insulators that do similar duty in the States are to the American. Each is characteristic of the climate in which it has proven fittest; each represents not only ingenuity and invention, but a vast amount of experience. The very familiar mode of protecting the copper wire used in the coils of electro-magnets and galvanometers, by serving it with a coating—single, double, or even triple—of cotton or silk, represents likewise the result of experience and ingenuity. In earlier days, before covered wire was an article of commerce, experimenters used to insulate the wires of their

ADDRESSES.

LAING, WHARTON, & DOWN, 82a, NEW BOND-STREET, LONDON, W., Electric Light Engineers & Contractors. Sole Operators for England of the Thomson-Houston system of Arc Lighting. Special Agents for the Edison-Swan Co.'s Incandescent Lamps and Apparatus. Manufacturers and Suppliers of every requisite for Arc or Incandescent Lighting, Dynamos, Lamps, Switches, Electroliers, Brackets, &c. Specialities in Primary Batteries for Electric Lighting. Venetian Shades and Glass, Carbons, &c. Temporary lighting on any scale at short notice. Estimates free. Telephone No. 3602.

JULIUS SAX, Electrical Engineer and Electric Light CONTRACTOR, RIDGMOUNT STREET, STORE STREET, LONDON, W.C.

Established 1855.

Specialities—Electric Bells, Burglar Alarms, Fire Alarms, Watchmen's Clocks and Fire Indicators combined, Water Gauges, Billiard Markers, Electric Vanes, Lightning Conductors, Speaking Tubes, Gas Lighters, Electrical Testing and Telegraph Instruments, Electrical Torpedo Apparatus.

Automatic Call Bells for Fire Stations, &c., fixed at all Stations under the control of the Metropolitan Board of Works.

Call Calls for Police Stations, Prisons, &c., as devised for and adopted by H.M. Home Office. Contractor to H.M. Post Office and War Office.

Electric Lighting—Domestic and Public. Estimates Free on Application. Eight Prize Medals awarded.

Telephone No. 3848. Telegraphic Address: "*Sax—London.*"

WALTER T. GLOVER & CO., Electric Wire and Cable Makers, SALFORD, MANCHESTER. Works: Bridgewater-street, Broughton-road, Salford; Salford Electric Wire Works, Salford; Springfield-lane Cable Works, Salford. Established 1868. London Address, 10, Hatton-garden, E.C.; Telegram, "Phonoscope," London; Telephone No. 6691. Manchester—Telegram, "Walter Glover," Salford; Telephone No. 1187.

Specialities—Glover's patent covered Gutta Percha Wire for Leading-in, Tunnel, and Underground Work. Specially covered Iron and Copper Wire for Aerial Lines. Fancy covered single and Double Copper Wire (Paraffined) for Telephonic and Bell purposes. All classes of Silk and Cotton covered Wires for Instruments and Dynamo Machines, Glover's Patent Electric Light Leads and Cables for the various systems.

All descriptions of Covered Wire and Cables for Telegraphic, Telephonic, and Electrical Work, as supplied to the Post Office and the principal Railways, Electric Light, and Telephone Companies.

ADDRESSES.

LAURENCE, PARIS and SCOTT, Limited, Electrical ENGINEERS and CONTRACTORS, GOTHIC WORKS, KING-STREET, NORWICH. Dynamos, Motors, Automatic Cut-Outs, Back Current Cut-Outs, Excess Alarms, Multiple Switches, and Switch Boards. Complete Electric Lighting Plants. Central Station Plants. Estimates on Application.

PHILLIPS BROS., Electrical Wire Manufacturers, The Lea Telegraph Works, HACKNEY WICK, LONDON, E., late of Macintosh-lane, Homerton. Established 1870. Telephone No. 5422.

Specialities—Gutta Percha, India Rubber, Compound, Cotton, Silk, Flexible Cords, Telephone Wire, &c., &c. Multiple and other Wires. Special Wires for Dynamo Machines. Electric Light Leads, &c. Patent Non-Inflammable Insulation for Incandescent and Arc Lighting and Dynamo Machines.

THE LONDON ELECTRIC WIRE COMPANY, ANCHOR WORKS, PLAYHOUSE-YARD, GOLDEN-LANE, LONDON, E.C. (Late of Wenlock-buildings, Ironmonger-row, E.C.)

Specialities—Covered Wires of all descriptions for Electrical Instruments, Dynamo Machines, Bell and House Work, &c. Fancy Paraffined Wires specially prepared for Telephone and other indoor connections.

JOSEPH BOURNE and SON. Works: DENBY POTTERY, near DERBY. London: 6, ST. PANCRAS STATION. Manufacturers of the well-known Stoneware Telegraphic Insulators and Battery Jars. Brown Stoneware. White Stoneware. Brown Porcelain. Porous Cells. Economy, strength, durability, and perfect insulation combined. Prize Medal, Paris Electrical Exhibition.

Makers of Mr. Slater Lewis's Patent Self-Binding Insulator.

J. G. STATTER and CO., Limited, Engineers, ALLIANCE ENGINEERING WORKS, WEST DRAYTON. London Offices, Prince's Mansion, 68, Victoria-street, Westminster S.W. Dynamos and Motors for all Purposes. Perfect Constant-Current System of Arc Lighting. Estimates free. Write for Lists.

PATERSON and COOPER, Electric Light and Power and Telephone Engineers. EUROPEAN WORKS, POWNALL ROAD, DALSTON (Near Haggerston Station). Contractors to H.M. Government, Leeds Corporation, &c.

Specialities—Phœnix Dynamos, Pilsen, Phœnix, and Clark-Bowman and J. F. Arc Lamps, Cardew's Voltmeter, Paterson's Electromagnet Am- and Voltmeter, Ayrton-Perry Am- and Voltmeters, Wallace Diamond Carbons, Switches, Safety Junctions, and Fittings for Arc and Incandescent Lighting. (Removed from 76, Little Britain, since Nov. 16, 1885.)

coils by winding a hempen string between the contiguous turns, and a sheet of paper between adjacent layers. Indeed, this primitive device has reappeared of late in the winding of the secondary wire on cheap spark-coils. When ocean telegraphy loomed forward as the practical problem of the telegraph engineer, new modes of insulation had to be devised. It is hardly too much to say that the spread of ocean telegraphy would have been delayed at least half a century had not an insulating material turned up which presented the proper mechanical and electrical qualities—which should not only be a splendid non-conductor, but which should also be water-proof, flexible, and mechanically capable of resisting enormous hydrostatic pressures. The material gutta-percha seems to have been designed by Providence for this especial purpose. Though many artificial substitutes have since been devised, the telegraph engineer would be decidedly put into an awkward fix should the supply of gutta-percha be (as seems not unlikely to be the case) seriously diminished. Indiarubber compounds, ozokerit, Trinidad bitumen, tarred hemp, and other materials there are in plenty; but none of them can so fully replace gutta-percha as to make this marvellous substance superfluous. There is yet room for further development in the art of manufacturing materials of this nature.

If we turn from the protection of wires and cables to the insulation of the working parts of dynamo machines and motors, we find that with the different conditions, mechanical and electrical, other materials are needed and other modes of applying them must be devised. Laminæ of mica are almost universally employed for insulating between the bars of commutators and below the binding wires of rotating armatures. Its great power to resist transverse forces, and its excellent anhygroscopic properties, alike recommend it for this purpose. In many cases the thin flimsy sheet, excellent as it is from the purely electric point of view, needs to be backed up mechanically by layers of varnished paper or other materials, which, though electrically weaker, are mechanically stronger. The best insulation in the long run is not by any means that which, when it leaves the testing-room, exhibits the greatest number of megohms of resistance: it is rather that which, whatever its nominal goodness, does not break down under the severer test of everyday work. Varnished canvas, Willesden paper, vulcanised fibre (so-called), and asbestos cardboard have all been used, and some of these are excellent in their proper place. It is said that sulphur is employed to insulate the armatures of certain American motors for tramcars. If we are not mistaken, the armature coils of Mr. Ferranti's new dynamos are held in place by a mixture of powdered glass and sulphur, which is run in while hot and firmly fills up the space between the coils and the frames in which they are clamped. Dynamos which are to work at high potential need to be insulated with special care. We know of one eminent maker who insulates the laminated iron cores of his armatures with several alternate layers of mica and varnished paper. Another lacquers his finished armature cores, before winding, with bath enamel, and heats them in the stove to harden it. Another uses the much-belauded Aspinall enamel. Another covers his cores with linen tape, which is then soaked with Scott's rubber varnish.

From dynamos one naturally passes to lamps. The insulation of arc lamps is an art in itself. It is not a very simple problem how to pass the current into and out of the carbon-holders when both are permitted to move, and when one or both of them must be perfectly insulated from the main frame of the lamp. No two makers carry out the insulation in the same way. A similar remark applies to the fittings for glow-lamps. At one time plaster of Paris—a substance objectionable because of its porosity—was largely used to bed the conducting terminals in the socket. For a time this substance gave way in favour of vitrite—a species of slag glass—which, however, declined in favour, as it was found to be very liable to fracture under unequal heating.

For the efficient insulation of main circuits in underground conduits, many devices have appeared. Mr. Brooks' plan of supporting the bare copper conductors mechanically by insulating washers at intervals inside a metal pipe, which then is filled with some cheap oil, is an excellent one where there are no gradients. A recent variation in this mode consists in winding a hempen rope in very wide spirals around the copper conductor in lieu of washers. The use of bitumen as a substance for insulating cable mains has been enthusiastically advocated by Major-General Webber. Another careful constructor—or rather, firm—runs bare copper strips in covered iron boxes of water-tight design, the copper strips reposing in nicks in stoneware pieces placed at intervals along the conduit. Mr. Ferranti, after trying many things, has adopted an insulation made of brown paper and shellac mechanically gripped between the inner and outer tubes of copper that he proposes to use as conductors. Using a Wimshurst machine and a battery of Leyden jars, he has failed to break down samples of this structure, though the potential must have been some hundreds of thousands of volts. This is not an unimportant matter.

It may be quite right, as some engineers have suggested, to test at regular periods the insulation-resistance of a circuit, or of a network of mains, by the use of a mirror galvanometer and a couple of Leclanché cells. But such tests, however many millions of ohms they show as the nominal insulation resistance, are utterly useless from the point of view of detecting probability of breakdown. What is wanted is a test executed with an electric potential exceeding that which will be habitually employed. No competent engineer would regard as a satisfactory test of the strength of a bridge an experiment made by observing a microscopic deflection of the girders under a force of a few pounds. The ordinary tests of insulation resistance made with galvanometer or Wheatstone's bridge are equally uninforming on the crucial point. For an insulation that is to be used at high potentials a high potential test is absolutely essential. The tendency to break down the insulation depends upon the electric tension or stress in the insulating medium; and the tension on the insulating medium is proportional (*ceteris paribus*) to the square of the potentials applied. A potential of a thousand volts applied to a given insulator produces in the substance of that insulator an electric tension a million times as great as that which would be produced by a potential of one volt. This distinction between the tension in the dielectric and the potential that causes it, is one often entirely overlooked by the careless thinker, who is too apt to use the words tension and potential as though they meant the same thing. But from the point of view of the liability of the insulator to be pierced by a spark, it is most important to observe the distinction. Doubling the potential will make the actual tension in the insulating medium four times as great, and quadruples the liability to break down. It is told—and the story, if it is not true, ought to be—that when Mr. Edison visited the Deptford station he was observed to be in a meditative mood, and when asked what he was thinking of, replied that he was pondering over that eighth of an inch of ebonite which was interposed between the ten thousand volts and human life. It may be perfectly true, as Sir William Thomson once observed, that ten thousand volts is no more dangerous in the laboratory than a circular saw is. But one would hardly like to risk a circular saw amidst an unsuspecting community with only an eighth of an inch of ebonite between them and instant death. The safety of the community—so recklessly defied in the ramshackle arrange

Digitized by Google

ments of overhead wires on high-potential circuits in the cities of the United States—cannot be disregarded here in England. The community demands protection from danger: to secure efficient protection is the aim and end of the art of insulation.

REVIEWS.

Electricity in Modern Life. By G. W. De Tunzelmann, B.Sc. The Contemporary Science Series. (Walter Scott and Co.)

This book aims at giving a short, clear, and connected sketch of the chief useful applications of electricity, their historical development, and the scientific principles underlying them. The author has, on the whole, succeeded admirably; and his book appears opportunely at a time when a rapid advance in electrical industry is recalling public attention to a favourite subject, and thereby creating a demand for books of this kind, addressed mainly to non-technical readers.

The reader is first of all treated to eight chapters of scientific principles. The fundamental facts of electricity and magnetism and the chief terms in use are explained. A chapter on force, work, and power, and another on the chief sources of electricity, lead up to the consideration of magnetic fields and lines of force. An excellent chapter on electrical measurement follows. In this the history of the growth of the electrical system of units is given, and the important influence on its development of both theoretical and practical men is clearly shown. The chapter on electrical machines is spoilt by the startling statements that it is impossible to use a series dynamo either for charging accumulators or for electroplating purposes, and that the three kinds of self-exciting dynamo are the series, the shunt, and the "separate circuit self-exciting" machines. The compound-wound dynamo is not mentioned. The names of Varley and Wheatstone are omitted in connection with the discovery of the self-exciting principle, although that of Siemens is given.

The opening portion of the book is necessarily rather briefly sketched owing to the amount of ground which has to be covered in order to introduce the remaining chapters (twelve in number), which are devoted to popular but correct descriptions of the numerous uses of electricity in modern life. A considerable space is devoted to the romantic story of the overland and submarine telegraph. The historical summary is very complete, and is written in a fluent and interesting style. The evolution of the telephone is fully gone into, and the working of an exchange is described. Among the comparative novelties introduced are Robertson's writing telegraph, the photophone, the water-jet transmitter of Chichester Bell, the Tainter-Bell graphophone, and the new Edison phonograph. The author usefully compares the improvement in the phonograph introduced by Bell and Tainter, who substituted a continuous curve for the separate indentations of Edison's original instrument, with that effected by Graham Bell in Reis's telephone by the substitution of an undulatory current for a series of intermittent ones. The author's apology for introducing the phonograph into his book is rather unnecessary, as the general public have always regarded the words electrical and marvellous as synonymous, and in this sense, at all events, the phonograph may be described as an electrical instrument. In the chapter on electric lighting, the work of Swan, in connection with the filament of the incandescent lamp, is made subordinate to that of Edison, and the work of Lane-Fox is not mentioned. The author lays proper stress on the important influence of the invention of the dynamo on the development of the glow lamp, but hardly states the almost equal importance of the improvements in the mercury pump. The remaining chapters of the book deal with various applications of electricity to traction, metallurgy, warfare, and medicine. A useful index is appended. The book is very well printed, and the illustrations are numerous and well executed. We can confidently recommend the book, not only to the class of readers for whom it is chiefly intended, but also to the average student of electricity, who will therein find much to interest and instruct him.

ON THE HEATING OF CONDUCTORS BY ELECTRIC CURRENTS.*

BY A. E. KENNELLY.

(Concluded from page 172.)

The Heating of Conductors Suspended in the Open Air Overhead.

For these measurements nine wires were suspended about 6ft. (180 centimetres) from the ground parallel, to each other, one foot (30 centimetres) apart and supported on glass insulators. The current was led through these wires in series, and the potential difference between points on each wire a measured distance apart observed in the usual way. The tests were made on two successive days, four wires being tried at once on the first day and six on the second, one wire having the benefit of a second trial. They were in the shade, and the temperature of the air was 28°C. by dry and 26°C. by wet bulb thermometer. The weather was calm, but there were at times, particularly on the second day, slight gusts and motions of the air—not amounting, however, to a steady breeze. The effect of these disturbances on the temperature of the wires was so great that the readings were all very unsteady and difficult to observe. On several occasions the effect of increasing the current in the wires was not only neutralised, but even apparently reversed, by an increased motion of the air. Consequently the results obtained have been much less reliable than those deduced from similar wires indoors. There can be little doubt that if the air out of doors were as tranquil as that in a closed room, the cooling of wires would differ in those places only in respect to radiation. This is of course seldom, if ever, the case, and the effect of the air's motion in assisting convection is very great. These results may fairly serve to indicate the maximum temperature elevation overhead wires can attain in calm weather, but to what extent the convective loss of heat can attain in windy weather is not known, and is probably many times greater than that here determined.

Fig. 5 shows the curves plotted from the observations. Owing to the variation in the readings some little judgment had to be exercised in selecting the best mean value. Two of the wires were covered with white cotton, one covered with braided and blackened cotton, while the remaining six were bare, soft copper wires, such as are generally used for overhead electric light conductors. The black-covered wire is shown to have maintained about 25 per cent. less temperature elevation than the bare wire of equal diameter and conductivity. On the other hand, the white-covered wires Nos. I. and VII. in the figure were sensibly hotter than the corresponding diameters of bare wire, the elevation of No. VII. being about 10 per cent., that of No. 1 nearly 50 per cent. in excess. This large excess in the latter case is, however, perhaps attributable to the fact, discovered in working out the results, that the conductivity of this wire was low and its behaviour may not have been reliable. The fact of the cooling of a wire being assisted by an insulating covering was pointed out on theoretical grounds by Prof. Forbes in his Paper already alluded to. He showed that the greater radiating surface so obtained more than compensated, up to a certain thickness of coating, for the poor thermal conductivity of the insulator. It appears, however, that with these wires tested the white covering formed an exception to the rule, the surface being probably less favourable to radiation. Curves Nos. IV. and V. represent the behaviour of the same wire on the two successive days, and show the temperature elevation to have been about 7 per cent. less on the second trial, owing perhaps to the greater degree of movement in the air on that occasion, as already mentioned.

Fig. 6 gives the estimated best mean values of the convection for each of the bare wires at various temperature elevations. These have been obtained by deducting from the total energy per linear centimetre the radiated loss as determined from the measurements indoors, and the difference is shown as convection in watts per linear centimetre. Owing to the great variation noticed in the convection, they cannot be regarded as more than approximations, but as far as 40°C. of rise they appear to be nearly straight lines, with the exception of the smallest wire. The excess of convection over that found within doors is also practically proportional to the diameter of the wire. Nor is it unreasonable that while with the convection in still air, where the energy of displacement is entirely supplied by the wire through conduction, the diameter of the wire may not play a prominent part; yet when the energy of the moving air is supplied from external sources, and the air passing round the wire carries off its heat, the increase of convection should depend upon the extent of the hot surface exposed, and hence be closely proportional to the diameter.

FIG. 5.—Curves representing the temperature elevation produced in different overhead wires out of doors, by various current strengths, in calm weather. — — — — lines refer to bare bright copper wires. — · — · — · — · — lines refer to white cotton-covered wires. — — — — lines refer to black cotton-covered wires. Wires suspended 6 feet from the ground and 1 foot apart in shade

The best mean values of the convection afforded by the experiments appear to be :

·00175 + ·013 d watts per linear centimetre per degree Centigrade elevation ;

d being expressed in centimetres, so that the convection from an overhead wire 1 centimetre in diameter would be eight times as great as within doors. Modifying the previous formula to these data, it becomes :

$$c = \cdot 886\, d \sqrt{\frac{d\,(m\ \pi\ R_t + \cdot 013\ t) + \cdot 00175\ t}{r\,(1 + \cdot 00388\ T)}}.$$

Simplifying, for bright copper, $m = 1$,

and $$c = 28 \cdot 9\, d \sqrt{\frac{570\ Q\ R_t + 7 \cdot 4\ d\ t + t}{1 + \cdot 00388\ T}}\ ;$$

and for blackened copper,

$$c = 28 \cdot 9 d. \sqrt{\frac{1140\ Q\ R_t + 7 \cdot 4\ d\ t + t}{1 + \cdot 00388\ T}}.$$

These formulæ involve the assumption, known to be inaccurate, that the radiation has the same value out of doors as within, the error involved not being large, and they can at best only fix the maximum elevation of temperature attainable in calm weather. By their use the following table has been calculated up to 1,500 amperes, although 300 amperes was the strongest testing current. To the latter limit, however, the accuracy of the table in representing the heating as actually estimated from the measurements may be judged from the following comparison between observed and calculated currents in the case of the four largest wires:—

Diameter inches.	5°C.		10°C.		20°C.		40°C.

Resumé of Results.

Wires in wooden panelling heated by currents are cooled by conduction under complex numerical conditions. As the temperature of the wire and panel rise, radiation and convection come into play. No simple and precise law can be given for the limiting temperature, but the limiting safe current approximately follows the diameter in sesquiplicate ratio; or in symbols, the best empirical formula is

$$c = ad$$

Also if the limiting safe diameter of an insulated panelled wire be such that twice the proposed full load upon it shall only raise its temperature 40°C., then the best formula is

$$d = .0147\, c^{\frac{2}{3}},$$

d being in inches and c in amperes; or roughly,

$$d = \frac{c^{\frac{2}{3}}}{70}.$$

A bare wire in still air cools by radiation and convection. The radiation follows the law of Doulong and Petit. It varies with the surface nature of the wire, and also, strictly speaking, with the surface nature of surrounding bodies. For practical purposes, however, the environment may be left out of consideration and the radiation of a bright copper wire may be multiplied by a coefficient which is 1·7 for a surface of thin shellac varnish, and 2·0 for a varnish of lampblack and shellac.

The convection for small differences of temperature appears to be nearly proportional to the temperature elevation, and depends, among other things, upon the form of the conductor. It also seems to increase slowly with the diameter of the wire, but more than this the measurements have not thus far determined. It may be taken approximately as 0·00175 watts per linear centimetre of all wires for each degree Centigrade of temperature elevation.

A bare wire in air out of doors is subject to a very great increase of convective cooling even in calm weather. The convection excess over that indoors may be roughly taken as $0{\cdot}013 \times d$ watts per linear centimetre per degree Centigrade elevation in calm weather, d being the diameter of the wire in centimetres.

A coating of black cotton of ordinary thickness on a suspended wire reduces the temperature elevation, but one of white cotton seems rather to increase it.

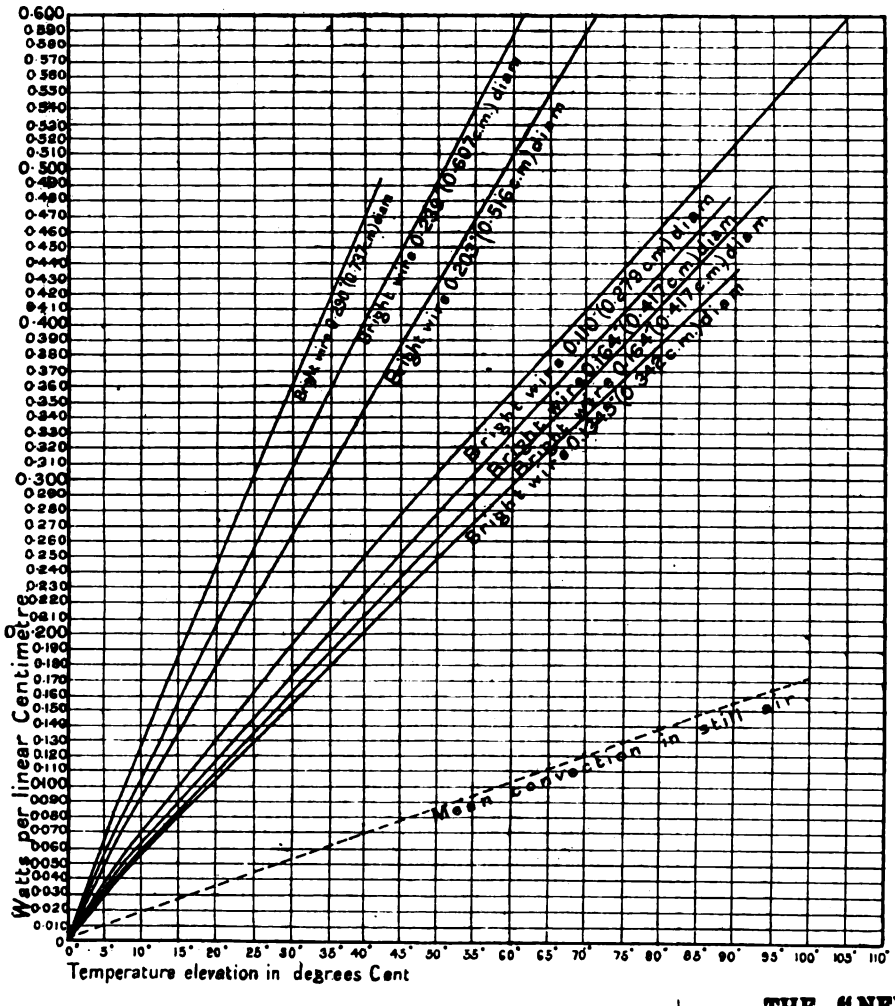

Fig. 6.—Curves representing the estimated mean values of the convection at different temperature elevations of six bare copper wires suspended on poles out of doors in calm weather.

THE "NEWALL" HIGH-SPEED ENGINE.

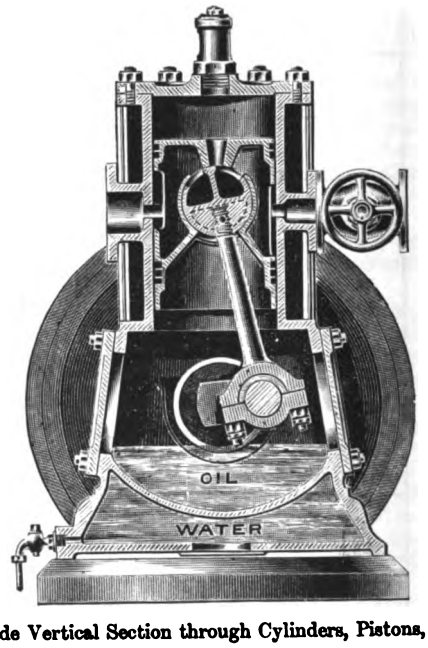

Fig. 2.—Side Vertical Section through Cylinders, Pistons, and Valves.

This engine, which is made by Messrs. J. F. Blyth and Co., of Millwall, has been especially designed for driving high-speed machinery; and, owing to the absence of eccentrics, rods, and the

Digitized by Google

usual valve gear, it is one of the simplest of engines. In a single cylinder, or one-tandem engine, there are only three moving parts, and in a two-tandem engine only five working parts in all. This engine has been in existence nearly two years, and during this time it has undergone many and various improvements. The "Newall" engine can be readily constructed on the simple high-pressure compound or quadruple expansion system. The chief aim has been to build a useful and economical engine taking up very small space, and to reduce the number of moving parts to a minimum. The "Newall" engine, it is claimed, is particularly adapted for running at very high speeds, is noiseless in action, and completely dust-proof, while the absence of long ports and passages makes it adapted to act as an air-pump or exhauster, inlet and outlet valves being entirely dispensed with. In compound and quadruple expansion engines the cylindrical oscillating valve is divided into four pockets or recesses for controlling the steam between the smaller and larger cylinders. During recent trials at the maker's works, both the high-pressure and compound engines are said to have given every satisfaction, the revolutions at which the machines were designed to constantly run at have in all cases been more than doubled, showing little or no friction, and the testimonials received prove that the "Newall" engine has met with considerable favour.

Fig. 1 is an external view of a double cylinder high-pressure engine, fitted with water relief valves, fly-wheel, and driving pulley

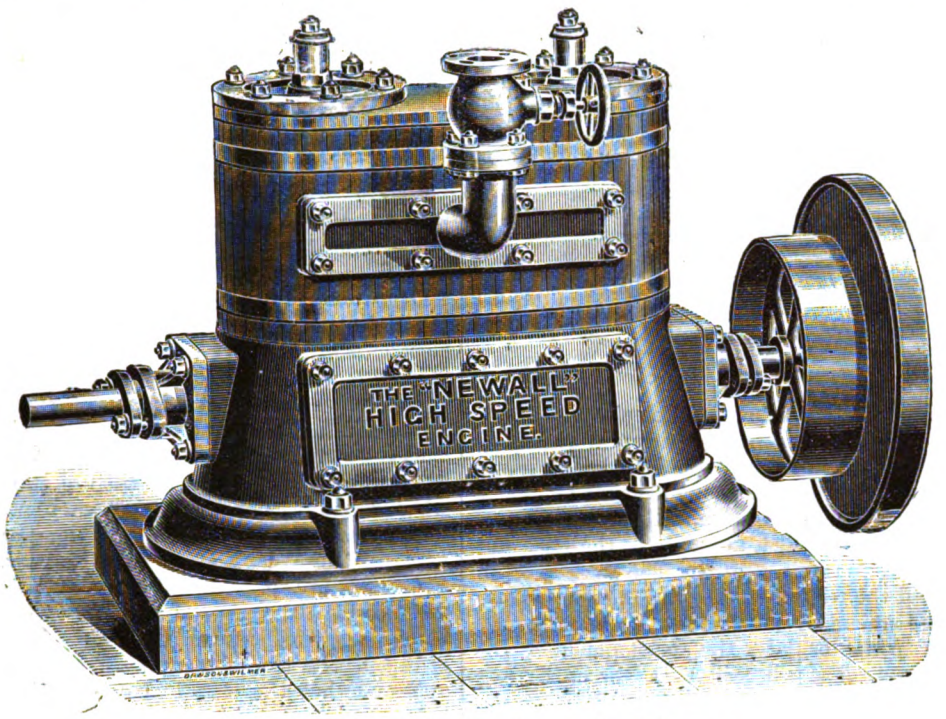

Fig. 1.—Double-Cylinder High-Pressure Newall Engine.

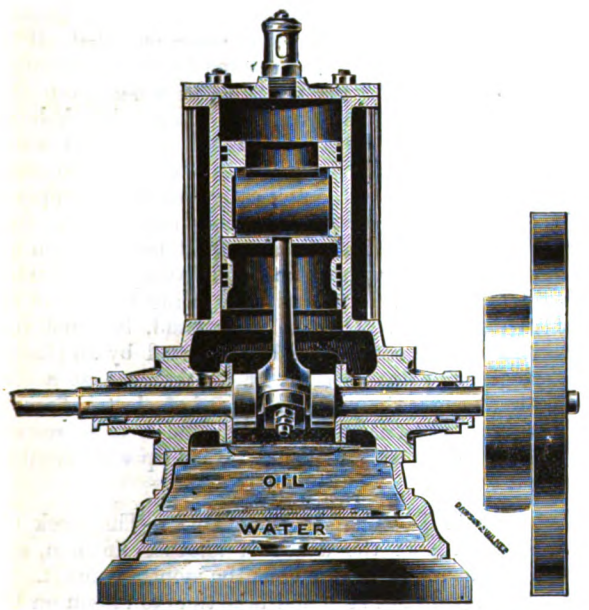

Fig. 3.—Front Vertical Section through Cylinders, Pistons, and Valves.

most economical in steam. Like most engines of its class, the pistons are single-acting in all cases; the connecting rods, brasses, and bearings are always kept in compression. The steam-controlling medium consists of a cylindrical oscillating valve attached to one end of the connecting rod, and formed with suitable ports and recesses, which open and distribute at the proper moment the steam to the various cylinders of the engine. The steam can be cut off at any portion of the stroke, while at the same time any required amount of cushion may be adjusted. The machine may be further for ordinary purposes. Figs. 2, 3, and 4 represent the side and front vertical sections and plan through the cylinders, pistons, and valves of the "Newall" engine. The chamber below contains the oil, separated by a partition formed with syphon holes for draining off any water due to condensation on passing the piston. The bearings are unusually long, and are grooved to retain the oil: a suitable recess, or pocket, formed in the top of the bearing, catching the oil and lubricant when agitated within the crank-chamber by

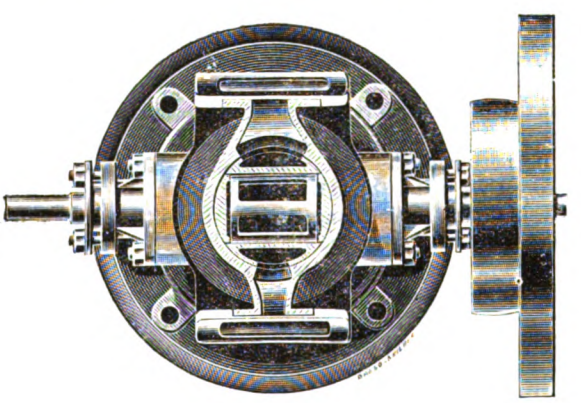

Fig. 4.—Plan.

the crank and connecting rod brasses; the lower half of the brasses are opened at the fillets, so that at every revolution the crank pins and bearings are saturated by the oil. The pistons are perfectly balanced, and working surfaces have large areas, and the makers assert that after two years' wear of the valves and pistons in a two-cylinder engine for driving the works, the tool marks were not worn out of the valve, which proves the friction to be slight. Several "Newall" engines are now driving dynamos, and would seem, owing to their simplicity, to be especially suitable for such work.

THE EDINBURGH EXHIBITION, 1890.

The following circular letter has been sent by the Secretary of the London Chamber of Commerce to the members of the Electrical Trades Section :—

DEAR SIR,—Referring to my circular letter of the 28th ultimo, relative to the terms which the Committee of the Electrical Trades Section of this Chamber have negotiated with the Edinburgh Exhibition authorities, I beg to advise you that the replies so far received from members of the Section are favourable to the acceptance of Mr. Lee Bapty's proposals. It is therefore suggested that members who intend to exhibit should send in their entry forms direct to the Exhibition authorities, with the proviso that they do so on the terms of Mr. Lee Bapty's letter to the Electrical Section. The question of appointing technical attendants at the Exhibition on behalf of the Section, the choice of judges, and tests, will be dealt with by the Committee of the Section in due course, but intending exhibitors must be reminded that applications for space should be made by the 31st instant.—I am, dear sir, yours faithfully, KENRIC B. MURRAY, Secretary.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 14, 1889.

The Western Union Company and the Telephone.—If one were to believe some of the statements appearing in the daily papers here, Mr. Jay Gould is not in a particularly happy frame of mind over his telegraphic interests. Long-distance telephone lines continue to extend in every direction, and during the past year the system has been perfected, not only in the East but through the Middle and Western States. The work is of an excellent character, and the results in the transmission of conversation and news are eminently satisfactory. It seems inevitable, therefore, that sooner or later the development of the long-distance telephone service will lead to a direct contest and conflict between the telephone and telegraph interests. The stories, however, told by the newspapers as to the injury done to the telegraph business by the telephone, smack of exaggeration. It is always hard to determine the exact amount of effect in the case of competition of this kind, and, so far, the telegraph returns have more than held their own. At the present minute, for example, the Western Executive Committee have recommended that the regular 1¼ per cent. dividend shall be declared, and that there shall be an extra dividend of ¾ per cent. This means 5¾ per cent. for the year, and would indicate that next year the rate will be 6 per cent., or even better. The actual figures for the quarter indicate phenomenal earnings. The net earnings for the September quarter are said to reach just over $2,000,000, while the estimate was only $1,750,000. This would beat the record, it is said, and practically place the Western Union Stock on a 7 per cent. basis again. I hinted at this possibility a month or two back, and the returns have been growing better all the time. It might reasonably be inferred, therefore, that just now the Western Union Company is not feeling the strain of any severe competition; but it does not follow that when the service of the Long-distance Telephone Company is complete everywhere, that Company will not devote a great deal of its time and a good many of its wires to the development of business such as is now done by the Western Union Company. It might be supposed that the telephone people were very much masters of the situation. They may be in some respects, but they also have their own little troubles. Thus, for instance, until within a very short time they have been at liberty to string their wires everywhere. Now, however, the electric railway business is rapidly pushing to the front, and it is now generally understood, as well by the public as by the experts, that telephone wires running near the wires of an electric railway are practically useless. Various remedies have been proposed, and some have been adopted with more or less benefit; but there is no denying the fact that the trouble has been one of the most serious that the telephone companies have encountered of late years. Thus, in Boston, the 400 miles of overhead conductor for the electric railway service with their heavy currents make a material difference in the conditions under which all the overhead circuits carrying small currents have been operated, and the Telephone Company there does not relish the situation at all. The solution that offers itself in large cities is the placing of the telephone wires underground in special conduits, where they will be out of the way of the heavy-current wires, so that they can neither suffer induction from them nor fall across them and render a fire possible.

The Boston Fire.—Speaking of the condition of affairs in Boston reminds me of the recent serious fire there, which resulted in a damage of about a million pounds. I understand that immediately after the fire, reports were cabled to England fixing on the electric wires the blame for the outbreak of the conflagration, and that there was something approaching a scare on the subject among those interested in electric lighting enterprises. If that be so, it will interest your readers to know that the mayor of the city, in a communication to the Board of Aldermen, has stated his belief that no evidence has yet been adduced to establish the truth of such statements. Mr. S. E. Barton, Chairman of the Electric Lighting Committee of the New England Insurance Exchange, a well-known body whose opinion is authoritative in such matters, says, in a letter to the Boston *Herald*, that as the result of pretty thorough inquiry, he disbelieves the electric wire theory on the subject. The fact is, the more the inquiry is being prosecuted the less reason does there appear to fix on electricity the blame of the fire. When the first reports of the fire went out it was boldly stated that it was caused by the crossing of time wires with electric light wires. Then the fact came out that the fire started after the arc light wires were out of operation. Then it was stated that the fire was caused by the crossing of time wires with the trolley wires of the West-End Electric Railway. These electric railway wires are protected by guard wires and are at some distance from the scene of the fire. Then it was said that the blame was fixed on the time wires by the stopping of some of the electric clocks just about the time of the fire. It then appeared that the clocks in question had stopped the night before, owing to a disconnection of the circuit, while the stoppage of the other clocks was directly attributable to the fire itself. Then it was said that the fire might have been started several hours in advance by the time wires, because they were not protected, whereupon it came out that all the wires of the Time Company were protected by fusible cut-outs. The probability is that the fire was due to some overheated flue. The day of the fire, Thanksgiving, was a public holiday. During such a holiday the district that was consumed would practically be deserted. At the same time it would be necessary to keep the fires up with practically two days' supply of fuel. It does not require a very vivid imagination, under such circumstances, to see how easily a fire could have broken out through defective heating apparatus, and having once started, could have got a good headway without being noticed in the very heart of a building. On the other hand, it is not very easy to see how the fire could have been started by an electric wire without giving palpable signs of its presence at a very early moment. That is the peculiar nature of electric fires, as everybody knows. Electricity has quite enough to be responsible for in these days without being loaded up with troubles that it has not caused.

The Accidents to Linemen in New York.—This week the New York papers report the death of another lineman, and some of them, as usual, are foaming at the mouth about it. It is really a pity they do not stop and take time to reason on the facts which they themselves print. It appears that in the case in question the lineman was working on one of the circuits of a suburban company. During the winter months the company turn on the current of their circuits at four o'clock. Notice to this effect is posted at the station, and the linemen are naturally supposed to be aware of the fact and to stop work. Late that afternoon, after four o'clock, without taking any trouble whatever to ascertain whether the circuit had gone into operation or not, the lineman in question climbed the pole and for the purpose of making a new connection cut the circuit with a pair of uninsulated pliers which he held in his bare

Digitized by Google

hand! That he was killed almost immediately goes without saying, and, of course, he was pretty well roasted before being taken down. If the public expect such accidents as these to be prevented by highly-insulated line wires and carefully-protected lamps, or even by placing the wires underground, they are, of course, utterly mistaken. So long as there is gross, wanton carelessness of this kind, men must pay the penalty of their lives. They do it in other industries, and it cannot be expected that electricity will prove any exception.

CORRESPONDENCE.

"THE ELECTRIC LIGHT IN ENGLISH TOWNS."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I desire to point out several important misstatements in the report of the Electric Lighting Committee to the Dublin Town Council, which appears in your issue of the 20th inst., on pages 172 and 173. In the schedule of prices the phrases used are unintelligible as they stand. The first should read "for the first 100 hours supply of the maximum supply demanded at the rate of 1s. per Board of Trade unit," and so on for the two other clauses of the sliding scale.

What is meant by "the tube containing the wires"? Again, the statements made would lead one to suppose that the cables —or what is presumably intended to refer to them—"the tube containing the wires"—were in contact with the cast-iron troughing. This is not so. It is rather a pity that the report does not show plainly what has been done and what a very simple though extremely good arrangement the engineers of the Company, working in conjunction with a very well-known and much-respected firm of cable manufacturers, have brought into extensive practical use, the canalisation being constantly under pressure, and showing very high electrical constants—the word constant being here used in its true sense. "High tension with transformers." *Really*, then, they must be infinitesimal in size, and are concealed in the lampholders, or something of the "Diehl" pattern, and the "high tension" must be such as no ordinary voltmeter will detect, as any of the usually accepted instruments show 110 on their dial if connected with the mains; and—a point of considerable importance, after the experience some of us have had in the Metropolis—that will be the indication in wet weather or fine weather, barometer high or barometer low. This says a good deal for the Siemens dynamos and Willans engines, as well as for the attendants in charge of them. —Yours, &c.,

C. H. Y.

December 23, 1889.

PHOTOGRAPHING ST. ELMO'S FIRE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is some years ago since I saw a paragraph in some of the scientific papers to the effect that a Berlin photographer had got an image of St. Elmo's fire on the top of the lance in the Amazon statue, but I cannot now trace the reference.

This has been a very puzzling thing to me for some time, especially bearing in mind the enormously greater length of the waves concerned in the propagation of electric (or electromagnetic) influences as compared with those of light. Dr. O. Lodge has been trying hard to get these waves shortened down to light waves, but here seemed to be a case in which, somehow, an electrical influence gave rise to waves which were shorter than those of light—being apparently ultra-violet, since the image on the top of the spear did not correspond to anything visible to the naked eye.

Do not, however, Mr. Shelford Bidwell's recent experiments on the effect of electrification on a steam-jet seem to throw some light on the phenomenon? And may not the brush discharge sometimes render aqueous vapour in the air opaque to the actinic rays, and not to the longer ones of the visible part of the spectrum?—Yours, &c.,

T. ARNALL.

City of Birmingham Surveyors' Department,
The Council House, Dec. 23, 1889.

THE HOOKHAM METER ACTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We have had our attention drawn to a paragraph in your issue of December 13th, headed "Curious Treatment of an Electric Meter." We presume your report is taken from the *Birmingham Daily Post*, as it is about as inaccurate and unfair as that paper's report. We enclose a copy of our letter to the Editor of the *Post*, which puts rather a different complexion on the case. We think you will agree with us that this paragraph should be headed "Curious Specimen of Birmingham Reporting." We should be glad to show your representative over the installation in which the meter was placed, as it would appear that the work had been very badly done from your report. Such, however, is not the case, as Chamberlain and Hookham's own engineer said it was one of the most complete he had ever seen. We trust you will give this statement of facts as prominent a place in your next issue as was given to your report in issue of December 13th.—Yours, &c.,

MONTAGU J. SCOTT AND CO.

100, Jermyn-street, St. James's.

Copy of Letter to Editor of "BIRMINGHAM DAILY POST."

CHAMBERLAIN AND HOOKHAM v. SCOTT AND COMPANY.

DEAR SIR: We have had our attention drawn to a report on the above case in your issue of December 5th, headed "Curious Treatment of an Electric Meter," and would point out that the report is inaccurate and misleading.

The facts as given in evidence were that the installation was worked by the gardener (as is very often the case in private houses), but all the gardener had to do with the meter was to take the readings night and morning, which he did when the meter worked. Your reporter evidently understands very little of electricity, or he would not have accepted, as he appears to have done, Mr. Young's (counsel for the plaintiffs) opening statement, made in a jocular way, as serious evidence. The joke about using the meter as a "hot water pipe" was only funny from the absolute impossibility of doing as Mr. Young suggested. As a matter of fact, the gardener never touched the meter. The plaintiffs' engineer, Mr. Holden, very naturally found the meter switched off, as our instructions were that if the meter stopped working it was to be switched off and left so until we saw it, and the gardener faithfully carried out our instructions. Next, two witnesses, who were with the plaintiff's engineer when he examined the meter, swore that the meter did not work when first switched on by the engineer, but that it was only when some 30 amperes (a considerable current) were passing that it began to work. Further, your reporter does an injustice to Messrs. Chamberlain and Hookham. They never lowered themselves to suggest that the gardener either had or should manure the meter; this was only another "funniosity" in the opening statement of Mr. Young, and was not seriously put forward as evidence.

Again, our defence was not that the meter would not work, but that it was unreliable.

Our client, Mr. P. C. Gilchrist, a scientific and practical gentleman, well-known in connection with the "Gilchrist" process for producing steel, refuses to have this meter connected to the installation.

Your report is consequently so unfair and unjust to us that we must ask you to insert this letter in your next issue.—Yours, &c.,

MONTAGU J. SCOTT AND CO.

THE HEATING OF CONDUCTORS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The articles now appearing in your columns, by Mr. A. E. Kennelly, on the "Heating of Conductors by Electric Currents," are most interesting and instructive—particularly so to myself.

When engaged with others in the autumn of 1887 upon a set of rules for the installation of electric light, we determined, if possible, to clearly define the limit of current to conductor, and in such a manner that tables could be compiled to meet it. Thanks to Prof. G. Forbes, we found this could only be attained by limiting the temperature of the conductor, due to current, to a certain number of degrees above air. Eventually the rule read as follows:—

"Conductors must be so proportioned to the current to be carried that in no case shall the temperature of the conductors exceed 18°F. (10°C.) above air."

As this limit has since been adopted by several of the fire offices, it is all the more satisfactory to find it confirmed by Mr. Kennelly, after a most careful investigation of the subject.

It is now evident beyond doubt that the limit is perfectly

Digitized by Google

safe, and at the same time gives full scope to the electrical engineer.

A table was subsequently drawn up from the formulæ of Prof. Forbes to meet the rule, but unfortunately it never received official sanction, owing to the doubt cast upon its reliability by Mr. Preece. It appears Mr. Preece discovered that some of the data relied upon by Prof. Forbes (dealing with the emission of heat) were not applicable to wires, hence the table was shelved pending further investigations. Mr. Preece, apparently, has been too much occupied of late to give the subject his further attention, a fact all the more regrettable, as he now finds himself forestalled.

Upon comparing the table referred to, as revised in May, 1888, with the table now issued by Mr. Kennelly at the instigation of the American fire offices, it will be found they practically agree for currents ranging up to 400 amperes. What difference exists is mainly due to the fact that the one allows for a greater thickness of insulation than the other. But when the specified diameters are converted into stranded cables of S.W.G., this difference absolutely vanishes.

In placing these facts before you, I cannot help regretting that, owing to the causes I have alluded to, the credit passes from this side of the water to the other—at least, so far as the fire offices are concerned.

But all honour to Mr. Kennelly. By a masterly treatment of the subject, he has now lifted it out of the region of theories into the region of facts; and I am well pleased to find the table and rules, in which I am interested, at length confirmed in so thorough a manner.—Yours, &c., H. HUMAN.

Guardian Fire Office, E.C., Dec. 23.

[An examination of the tables enclosed by our correspondent shows that they are practically alike.—ED. *E.*]

FLAMES AND ELECTRICITY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As this subject is again being alluded to in your columns, I hope you will allow me to direct attention to some points which require to be observed.

Electrical experiments with flames have been of two kinds. First, some parties have inserted instruments within flames, with the view of trying to discover the electrical condition of flames; but this is not the kind of experiments at present referred to in your columns. Second, can the surface of a flame receive a charge of electricity as if it were a solid body, and if so, how does a flame act? This is the subject of inquiry at present. Now, I maintain that it is impossible to place a charge of electricity on the surface of a flame. The current of hot air which is continually rushing up the sides of a flame prevents the possibility of a charge of electricity remaining on the surface of a flame. Again, the reason why an ordinary gas-flame assumes a tall, erect position is because the current of heated air around it forces the flame into the perpendicular position. Hence, when an artificial current of air is made to move a gas-flame to one side, we have in the bent flame ocular proof that such a current of air is then existing, and it is the application of this to a current of air, set in motion by a current of electricity, which lets us know which way the current of electricity is moving. The discovery that an insulated gas-flame could be trusted for the above purpose was made by me in 1839, and has been formerly noticed in your columns. It is a mockery of this subject to hold a candle or a spirit lamp to an electrical machine. The flame to be employed must be free from smoke, and must be insulated. A properly regulated coal-gas flame burning at the end of a long glass tube, with a small point instead of a burner, answers the purpose well. The oneend of the tube should be pointed for the gas to burn at the other, and should be provided with a brass stop-cock for regulating the size of the flame, and the stop-cock should have a rubber tube to bring the gas. In choosing a glass tube for this purpose attention must be paid to the character of the glass, for there are some kinds of glass which allow electricity to pass through them as fast as if they were a piece of metal, and there is no glass made which is an absolute non-conductor of electricity.—Yours, &c., JAMES JOHNSTONE.

8, Mercheston-park, Edinburgh, Dec. 23, 1889.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

ELECTRIC LIGHTING TENDERS.—The municipality of the City of Florence, in accordance with a decision of the Town Council, propose to grant by tender, and without any privilege whatever, a concession for the production and transmission of the electric current both for purposes of illumination and motive-power, for the use of the public. Tenders for the said concession will be received up to February 15, 1890. The principal clauses and conditions of the said concession are as follows:—1st. All the conductors are to be underground; 2nd. The difference of potential between the earth and all those parts which may be touched by those making use of the current must be less than 150 volts. In the principal conductors placed underground, however, 1,000 volts may be used; 3rd. The concession shall last 40 years; 4th. Applicants for the concession shall send in documents to prove and show their having obtained and worked other similar concessions with satisfactory results, at the same time stating which system they intend adopting for the production and transmission of the electric current; 5th and 6th. In order that tenders sent in may be taken into consideration, a temporary deposit of 25,000 Italian lire in cash or in Italian Funds must be made. For all further information concerning the above concession, and, moreover, to obtain a copy of the conditions in full as deliberated upon and voted by the Municipal Council, it is necessary to apply to the Secretary of the Municipality, Palazzo Vecchio, Florence—"Segreteria del Comune di Firenze, Palazzo Vecchio."

——— Tenders for the installation of the electric light at Segovia in Spain are invited, and will be decided upon on January 7, 1890. Particulars may be obtained from the Minister of the Interior at Madrid and from the Municipality at Segovia, to either of whom tenders may be sent.

THE BRITANNIA COMPANY, COLCHESTER.—A circular recently issued by this Company contains an illustration of a new Horizontal Radial Drill for drilling flanges at ends of long pipes, or holes in any position in the vertical sides of machines or machine frames. The table for holding the work has T slots on top and one side, and carries a pair of V blocks for holding pipes up to 24in. diameter. Illustrations are also given of a Horizontal Boring, Drilling, and Surfacing Machine for large work, with steel spindles, capable of boring holes up to 24in. diameter, and fitted with pulleys and gearing giving eight changes of speed; a Shaping Machine, fitted with many recent improvements, the gearing being so situated that the operator has complete control without changing position; and a No. 27 Stud Chasing Lathe, with capstan rest, for the production of screwed studs, joint pins, and small fittings. By means of the rest, the lathe will turn, point, and chase by the one operation.

MESSRS. PATERSON AND COOPER.—We have received from this firm advance sheets of their new electric lighting catalogue. An instructive table of approximate outputs of the "Phœnix" dynamo will be found on page 8, and some useful "Notes" on page 4.

REMOVAL NOTICES.—Mr. Harry South, of 10, John-street, Adelphi, informs us that, owing to increase of business, he has taken larger offices and show rooms at 10 and 12, Garrick-street, Covent-garden, W.C., where he will remove as soon as the necessary alterations are completed.

——— Mr. A. P. Lundberg announces his removal from Bowling Green-lane, Farringdon-road, E.C., to larger premises. His new address is Bradbury Electrical Works, Bradbury-street, Kingsland, N.

CALENDARS AND NEW YEAR'S NOVELTIES.—We have received from the Direct United States Cable Company a calendar for 1890 of original, not to say "striking" design. It consists of a "fist" clenched over a bundle of electric wires. At the base is a paper pad with a removable slip for each day in the year. It is certainly an attractive advertisement.

——— From the Commercial Company comes a copy of their well-known circular calendar showing the route of the Mackay-Bennett cables. A useful office calendar and effective advertisement.

——— Messrs. Crompton and Co. (Limited) send an octavo blotter with triplicate calendar for 1889-1890-1891, and a very handy, full-sized blotting-pad for office use, with flap calendar and memoranda. This is an improvement upon last year's pad, and will keep Messrs. Crompton's manufactures prominently before the users of the calendar.

JOHN A. ROEBLING SONS, AND COMPANY.—The new price list just to hand contains illustrations of McIntire's Electric Wire Connectors and Terminals, for which the firm are the American agents. Illustrations are given of electric light and hand-drawn telegraph connectors, and combination, branch, and solder-and-rivet connectors, and dynamo battery lamp and cut-out terminals, tools, &c.

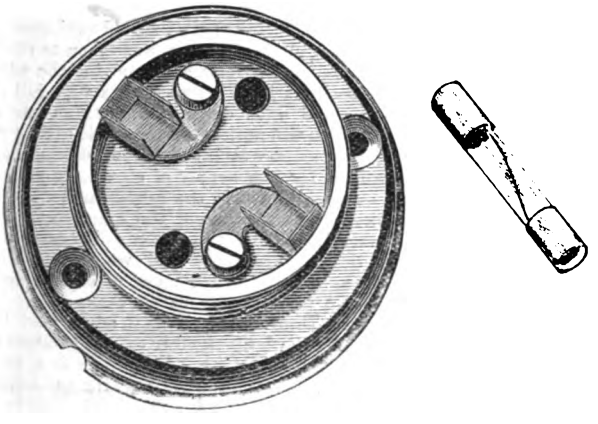
THE SCOTT INSTANTANEOUS FUSE.

One of the disadvantages of ordinary fuses is that they take some little time to act owing to their comparatively large mass, with the result that the current they will take momentarily on a short circuit before fusing is much greater than that which will fuse them when tried through resistances.

With a view to remove this defect a new fuse (see Figure), made of high conductivity wire, extremely fine, has recenly been brought out by Messrs. Laurence, Paris, and Scott. These fuses are of such small mass that the current through them on a short circuit never reaches anything like double what they will go at with a gradually increasing current. Repeated experiments with a fuse, intended to carry 1·5 amperes, show its fusing current, when gradually increased, to be from 2·25 to 2·6 amperes, and when short-circuited without appreciable resistance, through a magnetic cut-out, the latter must be adjusted to go at less than 4 amperes, before it will cut-out



at the same time as the fuse. Another experiment is to short-circuit the fuse through an ammeter, measuring up to 5 amperes, the needle simply giving a slight kick: a large ammeter is unaffected. Few people, with any regard for their instruments, would like to try this experiment with any ordinary fuse. The wire in these fuses is silver gilt. Another advantage of this fuse is the very good contact, the fine wire being soldered to the caps, and the caps making spring contact in three places on each cap in the fuse boxes. The fuse itself, though very fragile, is of a material that is unaffected by the atmosphere, and is so supported and enclosed that it is practically indestructible except by an excessive current. It is easily placed in the fuse box, and what is important from a fire insurance point of view, there is not the same facility for replacing a broken fuse by any handy bit of wire as there is with the ordinary fuse with terminal screws. There is also the 1in. break, usually stipulated for in fire insurance rules.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 9, 1889.

19,748. W. BROUGHTON. Manchester. Improvements in apparatus connected with incandescent electric lamps for the use of dentists, surgeons, and others.

19,794. A. P. TROTTER. London. A method of and apparatus for electrically reproducing designs at a distance.

December 10, 1889.

19,803. R. F. DEWHURST. London. Improvements in reflector adjusters for oil lamps, gas, or electric light.

19,831. C. M. DORMAN and R. A. SMITH. Manchester. Quick make and break electric switches.

19,835. M. PERLS and T. PERLS. London. Improvements in electrical signalling apparatus for the prevention of collisions between railway trains.

19,857. Sir C. T. FORBES, Bart. London. Improvements in secondary battery elements.

19,861. C. H. LOGAN. London. Improvements in secondary batteries.

19,875. N. NEWMAN. London. Improvements in electric gas lighters and extinguishers.

19,883. J. K. PUMPELLY and F. D. THOMASON. London. Improvements in electrical secondary batteries.

19,892. H. E. FOWLER. London. Improvements in machines or apparatus for welding metal by means of electricity.

19,899. W. P. THOMPSON. Liverpool. Improvements in or relating to electric batteries (M. W. Parrish, United States).

December 11, 1889.

19,946. O. D. LA DOW. London. Improvements in telegraph transmitters.

19,951. H. BAYLEY. London. Improvements in electrical switches.

December 12, 1889.

20,022. E. WILSON. London. A bi-planar electric switch.

December 13, 1889.

20,042. A. F. ST. GEORGE and A. ST. GEORGE. Redhill. Improved means for viewing distant and inaccessible objects by the aid of electricity.

20,059. C. R. G. SMYTHE and E. PAYNE. Glasgow. Improvements in and connected with electrical safety cut-outs and switches.

20,079. R. H. HUGHES and R. S. HUGHES. London. Improvements in fittings for outside and other electric lamps or lanterns.

20,032. R. T. TURNBULL. London. A method of and apparatus signalling numerals, letters, and other symbols by electric light.

20,105. G. L. HILLE. London. Improvements in electric batteries.

December 14, 1889.

20,106. G. L. HILLE. London. Improvements in and connected with electric batteries.

20,163. T. MACHIN. London. Improvements in propelling tricycles and other velocipedes by electricity.

CO-OPERATIVE TELEPHONES.

A meeting was held at the Memorial Hall, Manchester, on Monday last, for the purpose of receiving the report of a Committee appointed to consider the desirability of establishing a mutual economic system of telephones in Manchester and elsewhere. Mr. A. D. Provand, M.P., presided.

Mr. EDWIN GUTHRIE read the following report of the Committee:—

The Committee find that the principal patent (Bell's) will expire on December 9th next, and that no existing patents of any great importance will stand in the way of the free working of any new Company after that date. At present there are about 1,428 renters on the Telephone Exchange in Manchester and Salford. The rent paid in Manchester for the use of the Exchange telephone in most cases is £20 per annum. Conditional under-

Digitized by Google

takings have been received from more than 1,300 persons or firms to rent Exchange Telephones from the new Company at £5 per annum, and about 500 private telephones have also been applied for. The Committee are of opinion that the effect of the reduction from £20 to £5 would be to induce a very large increase in the number of users of the telephone, and these would in all probability shortly reach 4,000 to 5,000 Exchange renters, but in this report it is proposed to show the result upon the assumption of only 1,500 Exchange telephones of the new Company being rented in Manchester, and Manchester may be taken as a fair example of the probable results to be looked for in other towns. Your Committee find that the capital outlay to fully equip a plant for 1,500 Exchange renters, including 1,500 private instruments, and 500 extra private telephones, with two instruments each, would not exceed £18,000. The capital outlay for the equipment of 1,500 Exchange telephones, including the above estimated number of private telephones and extra instruments, would be about £12 per Exchange renter, against a capital outlay of the old companies of about £112 per renter, as exhibited by the last report and accounts of the Lancashire and Cheshire Telephonic Exchange Company (Limited). In comparing these two figures it must be observed that the estimates for the new Company are for a limit of one mile radius, while the other Company gives inter-town communication. For a larger number of telephones upon one Exchange, the capital outlay of the new Company would be certainly less than £10 per renter. Your Committee estimate the following to be the annual results of the working of the business upon the basis of 1,500 Exchange renters; on a larger number of renters the results would be proportionately more favourable—Income: 1,500 renters, at £5 per annum, for telephones within one mile, £7,500: 1,500 private instruments, at £1 each, £1,500; 500 private telephones, with two instruments, at £2 per annum, £1,000; total, £10,000. Expenditure: Rent, £300 to £500; manager, £300 to £500; assistants, £200 to £250; office sundries, £100; engineer, £300 to £500; 20 operators, 14s. each per week, £728; lady superintendent, £65 to £78; labour—six men and one boy maintaining wires, at £10 per week, £520; ten faultfinders, at 25s. per week, £650; materials and repairs, £500; way leaves and roof repairs, say £1,000 to £1,500; 10 per cent. to Government on income from Exchange wires, £750; sundries, including taxes, insurance, directors' remuneration, &c., £750; balance of income over expenditure, £3,837 to £2,674. Balance brought down, £3,837; less six per cent. dividend upon paid-up capital of £18,000, £1,080; leaving a balance available for reserve of £2,757, or not less than £1,594. The foregoing shows that a rent of £5 per annum would yield an ample return upon the capital outlay necessary to the equipment of an efficient telephone service for 1,500 Exchange renters. The actual working expenses of the National Telephone Company (Limited), and the accounts of the Dundee and District Telephone Company, which was absorbed by the National Company in 1885, proved the sufficiency of the estimates of income and expenditure. In explanation of the difference of the rent proposed to be charged by the new Company and the rent charged by the present Company operating in Manchester, it may be stated that the necessity for the larger charge of the old Companies is accounted for in part by the larger cost of equipment as compared with present contract prices, but in the main by the loading of the capital in respect of patent rights, concessions, and goodwill, the values of which are now about to expire. It is believed that a very large proportion of the capital of the telephone companies now quoted upon the Manchester Share List represents expenditure other than on the material equipment of the telephone service. As the proposed Company will have no extraordinary expenditure whatever, a capital of under £20,000 will answer all the estimated needs of the local service contemplated, while any increasing needs will always be represented by corresponding material value, whether by extension within the city of Manchester or in other parts of the district or elsewhere in the country. The Committee recommend as follows:—That a Company be formed under the Companies Acts with limited liability; that the registered capital in the first instance be £100,000 in £10 shares; that in the first instance £20,000 be issued for the purpose of providing for the proposed outlay in Manchester; that the headquarters of the Company be in London, with a central board there; that there be a local board of three persons in Manchester, and in each provincial district; that the co-operative or mutual system be recognised as the basis of the Company; that dividends be limited to 6 per cent. per annum upon the paid-up capital of the Company; that should the proposed rental of £5 yield a larger revenue than may prove necessary for the working of the Company and the creation of a sufficient reserve fund, the renters should have the benefit in a reduction of the rent of the telephones or the improvement of the service; that a committee be appointed and empowered to carry these recommendations into effect.—(Signed) Alex. Forrest, H. T. Gaddum, J. E. Longson, Edwin Guthrie, W. M. Mollison, W. Thomson, and Wm. Wadsworth."

The CHAIRMAN said the report afforded complete confirmation of the figures which were given in the preliminary circular issued to the commercial men of the city.

Mr. BILLING said he was positive that no system could work in Manchester with a subscription of less £10. He thought it was a great mistake to put forward estimates like those in the report, which he was assured would be doubled when the Company began operations.

Mr. GUTHRIE replied to this statement, and showed from an analysis of the working expenses of the National Telephone Company that the estimates were to be relied upon.

In answer to a question whether it was intended to make the interests of the users and the interests of the shareholders identical, the Chairman said it was particularly desirable that the renters should be shareholders, in order that there might be no conflicting interests in reference to the management of the Company's affairs.

On a question being asked as to the permission of the Corporation to erect additional wires, the Chairman said they had not yet approached the Corporation on the subject. When the Company existed they would see the authorities with reference to the matter.

Mr. PORTER moved—

"*That Messrs. J. S. Dods, Alderman Forrest, H. T. Gaddum, Edwin Guthrie, E. A. Hague, George Hahlo, J. E. Longson, W. M. Mollison, A. D. Provand, William Thomson, and William Wadsworth be appointed a committee to carry into effect the recommendations contained in the report submitted to this meeting.*"

Mr. HEWITT seconded the resolution, and it was carried unanimously.

A vote of thanks was passed to Mr. Provand for presiding, and the meeting terminated.

COMPANIES' MEETINGS & REPORTS.

Metropolitan Electric Supply Company (Limited).

Sir John Pender, K.C.M.G., presided over the second ordinary general meeting of this Company, which was held at Winchester House, Old Broad-street, on the 20th inst.

The SECRETARY (Mr. E. Cunliffe Owen) read the advertisement convening the meeting, and the report of the Directors was taken as read.

The CHAIRMAN, in the course of his remarks in moving the adoption of the report, said: The shareholders have before them a very full report of the work we have been engaged upon during the financial year which ended on September 30th last. You will notice that the whole of that period was taken up in obtaining parliamentary sanction for our schemes, and in the erection of central stations for the supply of electricity within the districts which have been allotted to us by the Legislature. We must, therefore, look upon this period as one wherein the foundations of our future success have been firmly laid, and I think you will share with the Board the conviction that this success is assured when you consider the large and important areas we are called upon to supply, and the enormous demand for the light which meets us on every side. As an illustration of the importance of our areas, I may state that it has been estimated that, putting aside the large number of non-residents who are employed in these districts during business hours, there is a resident population of upwards of 300,000. I am informed that the gas consumed in these areas represents a revenue of £337,506 a year, and, granting that we take from the gas companies a portion only of the lighting, we have every reason to anticipate a handsome income. Although we must look upon the past year as preparatory, it is satisfactory that during that period we earned a sum of £6,127. This amount was chiefly received from the supply of light at our Whitehall station. We have thought it prudent to place that sum towards the reduction of the general expenditure of the year, so that we may be enabled to start the present financial year with a comparatively clean sheet. Practically, the whole of the expenditure last year was capital expenditure, and we shall therefore have the full benefit now of the productive powers of those stations which are now completed. Full reference is made in the report to our Parliamentary history. The Board of Trade, acting under the powers conferred upon them by Parliament, decided to hold an inquiry into the various Provisional Orders and licences applied for by this and other companies. The inquiry lasted through the month of April, and was conducted by Major Marindin, and it formed a most important epoch in the history of electric-lighting enterprise. A vast amount of evidence was given, and the different systems proposed to be adopted were exhaustively discussed. In the evidence which I then gave, I stated that I should not consider this Company a great success until we had quadrupled our present capital. I am still of that opinion, and when I tell you that the total amount of capital embarked on the supply of electricity in London barely amounts to £3,000,000, whereas the capital of the metropolitan gas companies amounts to upwards of £13,500,000, I do not think you will accuse me of exaggeration. The result of the Board of Trade inquiry was that that body recommended Parliament to grant us rights in the areas mentioned in the report. The Board are of opinion that the areas—including, as they practically do, the whole of the theatres, and so many of the most important restaurants and public halls and buildings, the shops in Oxford-street and Holborn and the Strand, the offices in Chancery-lane, Lincoln's-inn, and elsewhere, and the valuable residential districts of Bloomsbury and Marylebone—are amongst the best in London, and will give us ample scope for our work. Moreover, it is satisfactory to note that to avoid the public inconvenience of frequently breaking up the streets, the Board of Trade have laid down the principle of only recommending for admission two companies using different systems into one area. If this principle is adhered to, future competition will be limited in extent—to the advantage, I think, both of ourselves and the public. At present we have only competition in a small portion of St. Martin's, and that has not affected us in any way. There are, however, two or three small companies at present supplying a certain amount of light in portions of the areas of this Company, and the Board are remonstrating with the authorities as to the unfairness of such competition, and we hope to be able to obtain the protection due to us as authorised undertakers from interlopers of this nature. The shareholders will understand that during these proceedings before the Board of Trade—and, indeed, until the recommendations they made had been confirmed by Parliament—we did not feel justified in completing our system of supply. As an instance of the uncertainty of our position during that period I may mention our Eccleston-place property, to which reference is made in the accounts. We purchased this site in February last, before the inquiry was commenced, for the purpose of supplying light in the districts of St. George's, Hanover-square, St. James's, Piccadilly, and Westminster. Owing to the decision of the Board of Trade we have been unable to utilise this site as we

Digitized by Google

intended, but we are in treaty for its disposal, and we hope to effect a satisfactory re-sale in a short time. The Royal assent was given to our Acts on September 2nd last. Since that time we have had authority to lay down mains and complete our system, and I think I shall be able to show you that the Board have lost no time in making use of the privileges they are now possessed of. I will now review our present position and prospects, and in the first place I will describe the stations we have erected and are erecting. As to the Whitehall station, when I last addressed the shareholders I stated that we were about to light some of the large hotels in the neighbourhood of that station. One of those hotels, the Hotel Victoria, we have been lighting ever since. In regard, however, to the others, the terms offered were so unremunerative and would have formed so bad a precedent that we considered it more prudent to decline them. From what I learn, however, people in these cases are, when a good installation is established, ready to give up their small installations in favour of the larger one. Besides these hotels, we have now been lighting for some time a number of buildings, among others the Avenue Theatre, the Turkish Baths, Hampton and Sons, St. Martin's Church, St. Martin's Vestry Hall, and the Garrick Theatre. We have also commenced to supply light to the huge block of buildings known as Whitehall Court. When those buildings are lighted—and they are now fast approaching completion—they will absorb the whole of the surplus light of that station. The Company hold a firm contract for the lighting of the whole of that gigantic block. The installation for the station at Sardinia-street, Lincoln's-inn-fields, was furnished and erected by the Westinghouse Electric Company, and you will be pleased to hear that the machinery has fulfilled all requirements, and has been working most satisfactorily; and from that time to the present there has been no hitch or failure in the supply of light to that or any other of the buildings we supply. We have taken on a total of 7,000 lights since the date of the opening, September 21st, and I think you will agree with me that that is not bad work for 13 weeks, considering that the cables had all to be run underground. I may explain that we were not permitted to open the streets until the Act was passed. Among the buildings we are now supplying from that station are the Gaiety Theatre, Holborn Restaurant, the Royal College of Surgeons, Exeter Hall, and many offices. I am told (but I have not been to see it) that the Holborn Restaurant is one of the most brilliantly lighted in London. In addition to this, we are under contract to supply a further 5,000 lights by the end of the year, including Drury Lane Theatre, the Government Record Office, Hansard's Publishing Union, Messrs. W. H. Smith's offices, Terry's Theatre, and various hotels, offices, and private residences. When all these lights have been taken on it may be considered that the present output of the station will be fully occupied. We have, therefore, determined to increase the capacity of the station by more than double, which can be done without further extension of buildings, and as we hold contracts for at least 6,000 lights, I have no hesitation in saying that this second installation will be fully taken up before its completion. I will now refer to the Rathbone-place station. The Board determined in February last to purchase a small station on this site as a going concern; but as the existing plant was small, and the demand for light in the district was very large, they accepted a tender of the Electric Construction Corporation for the erection of a powerful alternate-current plant. The first portion of the plant has now just commenced running, and its light-giving capacity is fully taken up. As soon as the plant is all at work—and we hope this will be early in March—we have in our possession contracts which will charge it to its full capacity, so that here again we shall be earning a maximum revenue as soon as the station can be got to run. With regard to South-mews station, which is to supply the western division of Marylebone, we have acquired a fine site behind Manchester square, the buildings on which are now nearly completed, and are practically ready to receive the machinery. The Electric Construction Corporation are supplying the plant for that station, and we are assured that it will be completed in April next. I am happy to state that there again we look forward to the best results, as no less than 50 per cent. of the gross output has already been applied for. As regards the Waterloo Wharf, we had accepted a tender from Messrs Johnson and Phillips to erect an alternate-current station on their site at Waterloo Wharf. Owing to negotiations with the London County Council we have not yet commenced to erect the buildings, but the machinery is in a forward state. We are also about to erect a station in the Strand district; and if we obtain the necessary powers we shall erect stations to supply Paddington and the western portion of the City area. We are also considering the advisability of erecting a separate station to supply Bloomsbury and Holborn, in view of the fact that the Sardinia-street station will prove inadequate for the requirements of these districts. It must be remembered that the erection of these stations involves also the laying down of the necessary mains, and this is by no means the least arduous part of our undertaking. We have already laid four miles of the underground mains from Sardinia-street, with very successful results, and we shall have eventually a complete network of underground mains traversing the whole of our district, extending over 35 miles. As, however, a considerable time must elapse before this work can be satisfactorily completed, and as it is impossible now to run any new overhead mains, the Directors have succeeded in coming to an arrangement with the London Electric Supply Corporation, whereby that Company has agreed on reasonable terms to hand over their existing overhead cables in districts allotted to this Company, but previously supplied by them, thus immediately enabling us to obtain a large revenue. I may tell you that we are working on the most friendly terms with the London Company, and we help one another when we can. I have always held that the less friction the better the machine. There is employment for their capital as well as ours. You will probably wish to know something about our present and future revenue. Our manager, Mr. Claremont, has reported that we are at present supplying about 15,000 lights from Whitehall, Sardinia-street, and Rathbone-place, and that he estimates that that will produce a revenue of about £20,000 a-year. He also states that that will be almost immediately increased to about 30,000 lights, with an estimated revenue of over £30,000 a year.

A SHAREHOLDER: Net?

The CHAIRMAN: No, gross. When the second installation at Sardinia-street is finished, the Rathbone place station fully equipped, and the Manchester-square station opened, we shall be in a position to supply from those four stations, allowing for a reserve of spare power, about 80,000 lights, with an estimated revenue of £89,250. As to these figures, you must consider that they are more or less based on the experience we have gathered of other installations in other places, and we believe those which I have given you to be as nearly correct as possible. We are dealing with a new business, and it is extremely difficult to get absolutely reliable estimates, but I think I can safely say that when our present capital of £500,000 is fully employed, we shall be supplying not less than 100,000 lights, and that our revenue will be at least £100,000 per annum. I believe that by the spring we shall have not only the whole of the capital engaged, but the whole of the installations I have indicated thoroughly at work, and producing very satisfactory results. I may further state that, as far as we can ascertain, the experience of gas and long-established electric companies goes to prove that there is only 60 per cent. of productive power used at any one time, and that 40 per cent. may thus be said to be in abeyance. We have based all our calculations on the maximum power being required, and therefore if experience and practice show that we have this 40 per cent. to spare, and can safely use it, it will give us a large additional revenue. In the autumn Mr. Edison paid me a visit and went over the Company's installations that were then established, and his observation was that the Board were applying the science of electricity in a thoroughly practical way, that they were not putting too many eggs in one basket, and that they were doing that which could not fail to be a success. Mr. Edison said that of all the cities in the world he knew of, there was no city that offered such a grand field for electric lighting as London, with its large areas and a great and comparatively rich population, and, at the same time, the worst weather that was to be found in the world. Mr. Edison therefore expressed his opinion that electricity would become positively a necessity in London more than in any other city. I have received a telegram this morning from Mr. Edison, who says, as to electric light companies in the United States: "Sixty companies earn from 6 to 20 per cent. Large numbers of them put earnings into extensions, owing to short capitalisation." In America, I may explain, they have comparatively small capitals, and as their requirements grow they put earnings into extension, and after they arrive at a certain point they generally add a considerable amount of "watered" capital, probably 25 to 30 per cent., so that the dividends now being paid in America of from 6 to 20 per cent. are actually paid upon the amount of "watered" capital as well. Otherwise, as Mr. Edison remarked, the dividends would seem too great, and too much competition might thus be created. Mr. Edison in his telegram goes into details of some special cases, and says, "Boston—capital $1,500,000, earns 13 per cent. this year; Harrisburg—capital $125,000, pays 20 per cent.; Reading—capital $130,000, pays 18 per cent.; New Bedford—capital $150,000, pays 6 per cent.; Rochester—capital $225,000, pays 8 per cent.; St. Paul—capital $250,000, pays 8 per cent.; Washington—capital $300,000, pays 6 per cent." Then Mr. Edison adds, "All our companies capitalised at between 25 and 30 per cent. more than actual cash invested." That shows you, gentlemen, pretty much what is being done elsewhere. London is at the present time a city of all cities in the world that is behindhand in electric lighting enterprise. However, we are now entering upon a new departure with a considerable amount of energy, and I consider that it will be a grave reflection upon the Directors and upon the scientific and practical men of London if they cannot do their work as well as it is done in other countries. I have the strongest possible belief that we are entering upon a successful career, and that our property, as a lighting property, will develop in as great a degree as gas has done. Therefore, with all confidence, I say that we have a great thing in hand. If people tell you that this is a flash in the pan, do not believe it. I advise you to stick to your shares, and you will find that you have a wonderfully good and promising investment. Some of my friends have told me that they have been advised that the thing cannot go on, there being no dividend this year. It was impossible to create and erect installations as we have been doing, and have them all running and earning dividends before the works were thoroughly established. We must have time to establish works, and our works are now in such a position that they will very shortly be producing very largely. At the same time, I have shown you that we cannot even now produce enough for the demand. I have received a telegram this morning from Berlin—a city which is very well and satisfactorily lighted—which states that the company in Berlin is paying 9 per cent. per annum, and that they expect a very large increase upon that, as they are now getting their stations into full operation. I think I mentioned to you at our last meeting that Sir George Elliot, Sir James Anderson, and other gentlemen on our Board had been for a long time closely connected with electricity, which we have shown has become a great power and a great benefactor. I think you will find from Lord Salisbury's speech the other day that he inferred that it had been probably the greatest factor in human progress in his time. When the Board took up this question of electric lighting they did so from a conviction that the time had come to do it. A great deal of money has been spent in speculative purposes, and a great deal of excitement was then caused. That has passed away, and in its place you have solid work. You are now getting real value for your money. I have great pleasure in reading you a telegram from Sir George Elliot, who would have been here to-day only he was called away to Egypt, and he sends me this telegram, dated Port Said, the 20th:—"Your general meeting of Metropolitan Electric Company takes place this day. This despatch is to express my regret at my inability to be present, and to add that, should you deem it necessary, you may state that, had I been present,

Digitized by Google

I should have expressed my opinion and belief in the prospects and solidity of the Company, and that with courage and patience the shareholders will be well satisfied with their undertaking and its dividend." Continuing, the Chairman said: I think I have now told you everything I know myself, and my views are unchanged. I hold the very strongest opinion that we are on the right road, and we are determined to pursue it with energy. I hope that when I have the pleasure of meeting you again you will bear in mind the remarks I have made to day. It will take some time to complete the works now contracted for, and to fully expend the money which has been subscribed. As soon as we require money we intend to put out a certain amount of debentures. I believe that we shall be able to get debentures at a low rate of interest, and if this is done it will be of great benefit to the shareholders. In the event of our requiring more capital, we shall come to the shareholders first and give them the advantage of taking up the new shares. I believe our property will become a very important one, and that those who hold on to their shares will reap the reward I have indicated. He then moved—

"*That the report of the Directors and the statement of accounts to September 30, 1889, submitted to this meeting, be and the same are hereby received and adopted.*"

Alderman Sir R. N. FOWLER, M.P., in seconding the motion, observed that it was unnecessary for him to add anything to the full remarks which had just been made by the Chairman. He only wished to emphasise the statement that until the Royal Assent was received to their Act they were not able to commence business, or take proceedings for beginning business; and therefore, as the shareholders would see, the Company had not had, until quite recently, an opportunity of earning a profit. Therefore what had already been done must be regarded as having been accomplished in a very short time, and not as a year's work.

Mr. BIGWOOD said that he was a stockbroker, and that balance-sheets played an important part in his profession. They had to be watched before advice could be given to his clients. He had looked into the balance sheet of this Company, and he had been amused at the entry of "sundry credit balances." Sundry debtors stood at £9,522. 18s. 3d., which was in favour of the Company, and was correctly expressed. When, however, he looked on the other side for "sundry creditors," he found "sundry credit balances," £42,305. 1s. 11d. He did not know what "sundry credit balances" meant, and he thought it was misleading. He also saw that they had borrowed from the bank £10,000, on which, of course, they paid interest, while on the other side they had at the bank £9,900, for which he presumed they received no interest. He also considered that the items of "Parliamentary expenses and Board of Trade inquiry £4,800," and "office furniture £670," showed a want of economy on the part of the Board. He wished the Company every success, and of its ultimate success he had not the least doubt.

Mr. GILES, M.P., said he considered the Chairman's statement very satisfactory as regarded the progress of the Company. It was clear that, as they only received the Royal Assent so recently, they could have done very little up to the present time in the way of earning money. He could not help thinking that the expenditure upon what they had already completed was very small. The shares were now standing at a good price, and it seemed to him a pity that the remainder were not issued.

Mr. HENDERSON inquired whether the overhead wires would have to be removed and replaced by others underground. He also inquired whether the shareholders would have an opportunity of paying up in full the balance due on their shares.

The CHAIRMAN, in reply, stated that practically all the expenditure that was incurred last year ought to go to the cost of the installations—that was to say, expenditure on capital account. As to the money they had borrowed, they were owing money to parties who had furnished them with installations, and they had not been in a hurry to pay so long as they were not pressed. They had, however, to be satisfied that the money was in hand if they should require it, and therefore they arranged with their bankers, who had perfect confidence in the Company, to place a certain amount of money at their disposal if they needed it This had been done, in order not to press unduly upon the shareholders for calls until the installations were at work, and the Directors could show that the money had so far been expended, and that the prospect of getting a return on it was not very distant. If, too, they had made calls, they might have depreciated the market value of the shares. He hoped Mr. Bigwood would see, from what he had now said, that the Directors, in what they were doing, were endeavouring to make this a class of property in which the public generally could have an interest and confidence. They did not issue the remaining shares because they believed that when they paid a decent dividend—which he hoped to do at no distant date—they would be able to borrow money at a very moderate rate; and they would see how much that would add to the value of their shares. They were trying to make the undertaking popular with the shareholders. As to overhead wires, the Government had laid down a law that they must be dispensed with in two years time. All the wires they were laying were underground. They had, however, as he had said, bought a certain amount of overhead wires from the London Company. He did not know that those wires would have to be taken down in two years, but if so, the Metropolitan Company would have had the benefit of them in the meantime, and he might say that they had been acquired on terms which made their purchase a good bargain. Their accounts, under the Act, would have to be made up to December 31st in each year, and they would have to issue supplementary accounts to the end of this year. When they did that they would also deal with the larger question of finance; and in sending out the statement they would intimate whether the shares might be paid up in full or not. It would create a little irregularity, but they were very anxious to meet the wishes of the shareholders on every point so far as they could do so. He then put the motion, which was carried unanimously.

The Auditors—Messrs. Deloitte, Dever, Griffiths, and Co.—having been re-elected,

The CHAIRMAN stated that, in the interests of the shareholders, a system had been established by which there was not only the usual audit, but a constant audit. They had also thought that the Company ought to have the most able and the best auditors who could be found, and he believed that Messrs. Deloitte, Dever, Griffiths, and Co. were second to none.

Mr. GILES, M.P., then proposed a vote of thanks to the Chairman and Directors. He quite agreed with the Chairman's remark that Englishmen ought to do as well with the electric light as had been done elsewhere. Looking at the list of Directors of the Company, he felt quite sure that they were competent men of business, and that they would make the concern as great a success as any body of men could do. He hoped they would not be shy in asking for more money when they required it.

The motion was seconded by Mr. BLANDY, who said that Sir William Thomson, the great electrician, in reply to questions put by him (the speaker) respecting the Company, said: I am only their consulting engineer, and I cannot say what the Company may be financially. But I know the people whose names are on the Board, and I know what splendid work Sir John Pender, Sir James Anderson, and Sir George Richards have done for the Eastern Telegraph Company, and that if the Company can be made a success you may consider that it will be.

The motion was carried unanimously.

The CHAIRMAN, in reply, said that the Directors were working with the greatest possible desire to make the Company a success. It was more than a question of money. They had, in fact, the greatest stimulus that men could have to carry out successfully an enterprise which he believed would have an important influence on this great City, and to show to other countries that Englishmen were not behind them in taking advantage of both scientific and mechanical progress. With the support of the shareholders, they hoped to carry the undertaking to a very successful issue.

The meeting then separated.

The Phonopore Syndicate.

A meeting of this Syndicate was held on Tuesday last, at the City Terminus Hotel, Cannon-street, Mr. Henry Kimber, M.P., in the chair.

The SECRETARY (Mr. Henry Parminter) having read the notice convening the meeting,

The CHAIRMAN said, in moving the adoption of the report, they recorded that day the accomplishment of the practical working of one of the greatest strides in telegraphic work which this century had yet seen. This meeting, with the exception of the statutory meeting, was the first ordinary meeting of the Syndicate, which commenced in a very modest way in a meeting under the presidency of his colleague, Mr. Philbrick, Q.C., at his chambers only two years ago. Then a few of them put some private capital together to co-operate with the inventor, Mr. Langdon-Davies, in proving the practical working and developing of his invention. His old friend, the late Sir Charles Wheatstone, was wont to describe inventions of this kind by referring to the portion of a century over which the discovery might be deemed to have been developed. He well remembered the completion of the Gramme machine, which, Sir Charles remarked, was an advance of a quarter of a century in electrical science, and he made the same remark with regard to his own fast-speed automatic telegraph, which accomplished from 415 to 420 words per minute. What Sir Charles Wheatstone would have said when they were now able to show that not only could that speed be attained and one message telegraphically sent at great speed, but a large number of messages could be in course of transmission by different operators without retarding the speed and without breaking down. He was inclined to think he would have said it was a stride of something more than a quarter of a century. They had proved by the testimony which had been laid before them that the phonopore was by far the best kind of multiplex telegraph hitherto discovered. It was not so likely to be thrown out of adjustment, and, when it was, easily capable, by the commonest operator, of being readjusted, and required no scientific aid for its readjustment. He might just refer to a paragraph in the report stating that there had been a demonstration in Spain, perhaps the most practical and decisive of all, under Government inspection, over a variety of ordinary telegraph lines from Madrid, through Saragossa, Barcelona, Taragona, Valencia, Teruel, Cuenca, and back through Madrid on to Guadalajara, a distance of 1,700 kilometres, or 1,065 English miles. It was impossible to overestimate the value and significance of the high success thus obtained. They had good testimony as to the value of this invention from the visitors to Mowbray House. Most of these visitors also went to St. Pancras, where they were allowed, by the courtesy of the Midland directors, to put up an installation between that station and Leicester, a distance of 99¼ miles. Sir Frederick Bramwell, President of the Royal Institution, had visited both places, and in his report to a gentleman who had asked him to examine the system, he stated that all of the things claimed to have been accomplished by the phonopore had been accomplished in his presence and to his satisfaction. He was informed by Mr. Langdon-Davies that he had been requested to read a Paper on the subject at the Royal Institution, and if Mr. Davies was unable to read his Paper the President had offered to read it for him if he would lend the necessary instruments. They had found it advisable to purchase another patent from Mr. Langdon-Davies, called the rate-governor. He would not go into any scientific details, but it was a very valuable invention.

Mr. LANGDON-DAVIES, at the request of the Chairman, made a few remarks, and stated that one of the most important of the experiments made proved that the Phonopore Telegraph could be worked upon submarine cable lines. This was proved from the fact that when he was at the Hague he put the instrument there in connection with the cable crossing the North Sea to the English shores. The England end of this cable was joined to another cable, which again crossed the North Sea back to Holland, and the Dutch end of this cable was connected with Amsterdam. The Phonopore telegraph was worked on this cable in connection with the ordinary telegraph between Amsterdam and the Hague, passing twice across the North Sea *vid* England, and duplex working was obtained. Other experiments were made, which showed that the Phonopore system could be successfully applied to cables of various lengths, and he saw no reason why, if, as they had already proved, it would answer on cables 200 miles long, it should not as successfully work on cables 2,000 miles long. So satisfactory were the experiments that approaches had since been made by the administration of the Government telegraphs in Holland and the representatives of the State railways and the Dutch railways, for the adoption of the phonopore by those lines, who had decided to adopt it.

The CHAIRMAN then moved the adoption of the report.

Dr. BAINES seconded the motion, which was agreed to.

On the motion of the CHAIRMAN, seconded by Mr. E. H. POLLARD, Messrs. A. B. Isaac and F. A. Philbrick, Q.C., were re-elected Directors.

The Auditors having been elected,

Mr. POLLARD said they were not previously aware of what Mr. Langdon-Davies had to tell them as to the result of the experiments in Holland, and such intelligence as had been given to them could not be allowed to pass without some recognition at the hands of the shareholders. He would ask them to respond heartily to the proposal he had to make, and that was that a vote of thanks be recorded on the minutes of that, the first annual regular meeting, to Mr. Langdon-Davies for his untiring efforts, and for the splendid results he had obtained.

Mr. PHILBRICK, Q.C., seconded the resolution, which was carried unanimously.

Mr. LANGDON-DAVIES briefly replied, expressing his belief that he would be able to announce as satisfactory results over 2,000 miles as he had achieved over 200 miles of cable.

Mr. LANGDON-DAVIES proposed a vote of confidence in the committee and secretary, which was carried, and the meeting terminated.

NEW COMPANIES REGISTERED.

NORTH AFRICAN GAS SYNDICATE (LIMITED).—Registered by H. C. Eliott, 143, Cannon-street, E.C., with a capital of £30,000 in £1 shares. Object: to carry on the business of a gas or electric light company in the towns of Algeria and other parts of Northern Africa. There shall not be less than three nor more than five directors, the first to be appointed by the signatories. Qualification, £100. Remuneration, £50 each, and 10 per cent. on net profits after 10 per cent. dividend.

WREXHAM AND DISTRICT ELECTRIC SUPPLY.—This Company is registered with the object of forming centres in Wrexham, or within the surrounding hundred of Bromfield, both in Denbighshire or elsewhere, for the generation and supply of electric power, and the lighting of public and private buildings. Capital, £20,000 in £5 shares. Registered, December 19th, by Abbott Jenkins and Co., 8, New Inn, Strand, agents for Lewis and Son, Wrexham.

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 20th amounted to £5,644.

EASTERN AND SOUTH AFRICAN TELEGRAPH COMPANY (LIMITED).—The Directors notify that the coupons due on January 1st on their Five per Cent. Mortgage Debentures will be paid on and after that date at the banking house of Messrs. Barclay, Bevan, and Company, 54, Lombard-street, E.C. Coupons should be left three clear days for examination.

HALIFAX AND BERMUDAS CABLE COMPANY.—The coupons of the Four and a Half per Cent. Debentures of this Company, due on the 31st inst., are payable on and after that date at the banking house of Messrs. Dimsdale, Fowler, Barnard, and Dimsdales, 60, Cornhill.

WEST AFRICAN TELEGRAPH COMPANY—The Board of this Company announce the payment, on January 1st next, of an interim dividend of 3s. 6d. per share for the six months ended June 30th last.

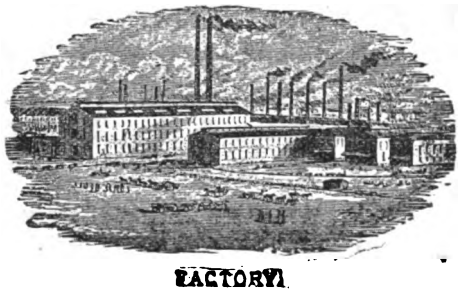
WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 20th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £4,048.

STOCK EXCHANGE.—The Committee have appointed Saturday, the 28th inst., as special settling day in the Brush Electrical Engineering Company (Limited), ordinary shares (Nos. 1 to 63,416) and Preference shares (Nos. 1 to 63,416), and the National Telephone Company (Limited), First Preference Shares (Nos. 1 to 15,000) and Second Preference Shares (Nos. 1 to 15,000); and they have ordered these securities to be quoted in the Official List.

THE NON-CONDUCTOR OF ELECTRICITY.

VULCANISED FIBRE,
PATENTED.

This new material is supplied in two qualities, Flexible and Hard.
The FLEXIBLE is a substitute for Leather, Rubber, Gutta Percha, &c., and is extensively used by Brass Founders, Axle Makers, Hydraulic, Sanitary, and other Engineers, Pump Makers, Carriage Builders, &c.
It makes the best Hot and Cold Water Packings, and for Axle Washers of all kinds it is unequalled.
The HARD is a substitute for Metals, Hard Wood, Ivory, Vulcanite, Ebonite, &c., and is a good Insulator.
Sold in sheets, 5ft. 6in. by 2ft. 6in., varying in thickness from 1-50in. to 1in.



FLEXIBLE, 2/- per lb.; HARD, 2/3 per lb.

MOSSES & MITCHELL, 70 Chiswell-st., London, E.C.

JABLOCHKOFF'S

DISTRIBUTION PATENT

(Being a Patent for "Producing and Dividing Electric Light," No. 1996 of 1877.)

THE UNITED ELECTRICAL ENGINEERING COMPANY (LIMITE

Are Proprietors of the above Patent, and Warn the Public against Infringement.

The following are Licensees:—

Anglo-American Brush Electric Light Corporation, Limited.
Crompton & Co., Limited.
S. Z. de Ferranti.—London Electric Supply Corporation, Limited.
W. T. Goolden & Co.
Hammond & Co.
Wilson Hartnell.
Johnson & Phillips.
Laurence, Paris & Scott, Limited.
Malder Brothers & Co.
Paterson & Cooper.
Ernest Scott & Co.
Siemens Brothers & Co., Limited.
J. G. Statter & Co., Limited.

3, Prince's Mansions, Victoria Street, Westminster.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 607.—Vol. XXIV. FRIDAY, JANUARY 3, 1890. Price Fourpence.

NOTES.

We this week publish as a supplement a map showing the Metropolitan districts which have up to the present been allotted to various electric supply companies. The total area covered amounts roughly to about 15 square miles, and extends from Rotherhithe and Deptford on the East to Kensington on the West, and from Wandsworth on the South to Marylebone on the North. With the exception of the City, within which no company has as yet obtained statutory powers, the territory already allotted is the pick of the London district. Thus the ground covered by the Metropolitan Electric Supply Company comprises practically all the London theatres, the majority of the big hotels, the busy district of the Strand, and the wealthy residential district round Manchester-square. The area allotted to the London Electric Supply Corporation is largely composed of West End shops and private residences; while the smaller districts, worked, either separately or in competition with the London Company, by the St. James's Company, the Chelsea Company, the House-to-House Company, and others, are of a superior residential character.

The Metropolitan companies do not, however, intend to rest on their oars, and there are numerous applicants for the overgrown parishes of St. John, Hampstead, St. Pancras, and Paddington, while four companies are anxious to supply current within the City. Should all these applications be acceded to, practically the whole of the area included in our map will be adorned with the distinguishing colours of the various supply companies.

We are glad to learn that the question of "blocking Orders," to which we referred in our issue of December 20th, is occupying the attention of the Committee of the Electrical Section of the London Chamber of Commerce, who have addressed the following circular to the leading supply companies:—"The attention of the Electrical Section has been called to the fact that many of the notices which have been given by the local authorities of their intention to apply for Provisional Orders have been given with a view of blocking the extension of electric lighting, owing to gas interests or other causes. The matter will be brought forward at the next meeting (28th inst.), and it is hoped that you will communicate to Mr. Trotter, the Correspondent, any corroborative evidence of such action as you are able to give, together with as many details as possible."

It is to be hoped that sufficient information will be forthcoming to enable the Committee to judge of the reality of the danger to electric lighting from the obstructive tactics of many of the local authorities. Information on this subject, even from those who do not receive circulars, would, we are sure, be greatly valued by the Committee.

On Monday evening last a fire took place at 8, Grosvenor-square, the residence of Mr. W. A. T. Amherst, M.P., the newspaper report of the occurrence adding that the origin of the fire had still to be inquired into, but there was a theory that the cause was an overheated electric wire. In the same way that the Boston fire and the New York fatalities have recently been made convenient pegs upon which to hang sundry advertisements, the unfortunate episode in Grosvenor-square afforded Mr. Edward Palliser an excellent opportunity of injuring a trade rival. "I see," said Mr. Palliser, in a letter to *The Times* of Wednesday, "there has been an accident in Grosvenor-square, said to be due to the heating of an electric wire. If so, it *must have been a wire connected with a high-tension system*" (the italics are our own). Why the overheating of an electric wire must necessarily be caused by a high-tension current is not at first sight apparent. In the next sentence, however, we are informed that the St. James' and Pall Mall Company, which was inaugurated by Mr. Palliser, is now ready to supply the harmless low-tension current. Mr. Edison's alarmist contribution to the *North American Review* was, we suspect, mainly inspired by the hope of damaging a rival system, but the effective use which has been made of this article at Barnsley might, we think, have warned Mr. Palliser that these one-sided statements do harm to electric lighting generally.

For the probable origin of the fire we have only to peruse the following extract from a report made by Mr. Musgrave Heaphy, and published in a letter from Major Waller in yesterday's *Times*:—"The conductors were in contact under the floors, they were unencased and fastened by metal staples. Among the few places that I was able to examine I found that a staple had cut into the insulation. The conductors in another place were in contact with the bell wires." With wiring of this class a fire was only a matter of time, whether the house was connected to a high or a low-tension system, and it is satisfactory to learn that the London Electric Supply Corporation have for

Digitized by Google

some time past refused to supply current to houses in which the wiring is not according to their own specification.

NOTHING is more surprising in connection with the scare as to the dangers of electricity, which is now subsiding in the United States, than the fact that a whole series of alarming reports has come before us in rapid succession, although high-tension currents have been largely in use for several years, and have not latterly increased to any great extent even in the towns where the excitement has been greatest. No doubt the explanation of this is to be found in the heated state of the public mind, and in the skilful use made by opponents of electricity of any substratum of fact which they could discover here and there. We have already drawn attention to several instances—such as the Boston fire—where, on investigation, no proof has been forthcoming to connect electricity with the disasters laid to its door; and we now wish to utter a word of warning as to the cause of the gas explosions in the New York subways, which have, without hesitation, been put down to electricity. We think that the gas interests have, in any case, little cause for the self-congratulation with which, according to a New York correspondent, they appear to view these events; for, whatever the cause of these explosions may be, there can be no question that the gas would not be in the subway if the gas companies did their work properly and kept the gas where it ought to be—that is to say, in the gas mains. It seems indisputable that the leakage of gas from the mains is often very great, and so long as this is the case there must be danger.

IN London we have had at various times explosions very similar to those which have lately occurred in New York, and these have taken place under circumstances that rendered it impossible to attribute them to electricity. For instance, a very serious explosion in the Tottenham Court-road district some years ago—the most serious case that we remember—took place long before any electric light mains were even contemplated in that district. We recommend electrical engineers to consider this question seriously, for while it is quite possible that leakage from their conductors may cause explosions, it must not be lost sight of that coal gas has no right in their conduits, and that its presence, especially in wet or damp situations, is very deleterious to many otherwise good insulating materials, and may cause such injury that, beyond and quite apart from the risk of explosions, it will ultimately render necessary the replacement of cables which have, by its presence, become too seriously lowered in insulating qualities.

ALTHOUGH the figures given by Mr. CROSBY in his interesting article on "Practical Points in Electric Car Service," which we print in another column, are not entirely founded on ascertained fact, yet they form a sufficiently valuable contribution to the somewhat scanty literature on electric traction. Mr. CROSBY works out the average cost of electric traction per car mile on the four lines referred to by him at a little over 2½d. Another important relation which is brought out in this article, though it must be received with some reserve, since it is founded only on the data of two lines, is that on average roads only 44 per cent. of the 24-hour capacity of the generating station will be actually used on the cars. Mr. CROSBY's figures also show that on an average every E.H.P. hour in the station will produce one car mile of service on the line. It is certainly satisfactory to find that the experience on the four lines tested by Mr. CROSBY is that heavy gradients do not increase the average power required to the extent which might have been anticipated. The strain of gradients upon both generating and motor plant is, however, perhaps best shown by the maxima. Thus, at Richmond on a 9 per cent. gradient 25·6 horse power was the maximum required to start a load of 8,500lb., while at Cleveland on a very slight gradient only 15 horse-power was required for a much heavier load. Mr. CROSBY very aptly points out at the end of his article how greatly the coal bill may be modified by the handling of the variable resistance on the car—a fact which has not, we think, been sufficiently recognised up to the present.

THE wreck of the "Tenby Castle," off Holyhead, resulting in a loss of 11 lives, has again called attention to the question of electrical coast communication, the fatalities in this case, as in so many others, being due to the delay in apprising the nearest lifeboat station of the wreck until too late to save all the lives. A man on horseback had to be sent from the coastguard station, five miles distant, there being no telegraph line connecting the two points, although situated at a dangerous part of the coast. We are glad to notice that Mr. ROBERT BAYLY is again writing warmly on the subject in *The Times*.

THE Medical Battery Company have written to us with reference to our editorial note on 13th ult., stating that they said something different from what we alleged they had said. We do not dispute it; but, all the same, they also said what we ascribed to them, the words being copied from the advertisement columns of the *Standard*.

Telephonic Development in Germany.—Telephonic communication has lately been established between Berlin, Cottbus, Forst (Lausitz), Guben, Spremberg, and Gorlitz.

The "Electrical Review" of New York.—This journal has now taken offices here at Bridge House, 181, Queen Victoria-street, where all communications are to be addressed to Mr. Charles Ffrench.

Bremen.—The Electric Lighting Committee has decided that all mains must be laid underground, but that the roads are not to be disturbed. The conductors are all to be placed in pipes under the footpaths.

St. Margaret and St. John's Vestry.—At the last meeting of this vestry it was decided, by 12 votes to 4, to refuse permission to the National Telephone Company to lay down pipes to carry telephone wires.

The Institution of Civil Engineers.—This institution, which was founded on January 2, 1818, has now on its roll 1,673 members, 2,698 associate members, 19 honorary members, 436 associates, and 978 students—together 5,804, against 5,616 at the same date last year.

The Telephone in Japan.—The Mikado has had constructed, at the cost of the State, a line of telephone between Yokohama and Striznoka, a distance of about 100 miles. It is the first telephone applied to the public service in Japan, and has so far been completely successful.

"Le Progres Postal, Telegraphique et Telephonique."—This is a weekly journal, published in Paris, and the special feature of which will be the publication in it of all official documents relating to the telegraph and telephone service which are likely to be of interest to the French public.

Eisenach.—The Town Council of this town has agreed to the contract made with the Berliner Electricitatswerke for the electric lighting of Eisenach. The town is to get 2 per cent. of the profits and 10 per cent. reduction for public lights. The work must be completed within one year.

Telegraphic Communication with the French Colonies.—Among the resolutions passed at the recent French Colonial Congress were two in favour of cables being laid between Réunion and Madagascar, and from there to the coast of Africa, and between Australia and New Caledonia.

Altona.—The Altonaer Quai und Lagerhaus Gesellschaft invites tenders for the electric lighting of the Altonaer Elbquai by 42 arcs and 80 incandescents. Applications must be made before January 19, 1890, to the Society, from whom all necessary information may be obtained on payment of 15 marks.

The Rubber Monopoly in Brazil.—The news regarding the establishment of a rubber monopoly in Brazil has been confirmed in despatches received by rubber merchants both in London and in Paris. The merchants of France and the United States have already appealed to their Governments to protest.

Copper.—The stock of copper in and afloat for Europe, according to Messrs. H. Merton and Co.'s statistics, diminished by 1,137 tons last month. At the end of the year 1888 the supply was 104,105 tons, and it is now 98,847 tons, having been as high as 124,876 tons on March 31, 1889. At the end of 1887 the total was only 42,301 tons.

The "Centralblatt" and the "Elektrotechnische Zeitschrift."—The *Centralblatt für Elektrotechnik*, edited since 1879 in Munich, has been incorporated with the *Elektrotechnische Zeitschrift* of Berlin, and will appear under this latter title in Berlin, with Mr. Uppenborn as editor. The united journal will in future appear weekly instead of fortnightly, the price remaining unaltered.

Brighton.—At the last meeting of the Town Council a letter was read from the Board of Trade, enclosing the report of Major Cardew, on his recent inspection of the installation of the Brighton and Hove Electric Light Company. The communication stated that the Board proposed to act upon the report, and to insist that the Company shall reconstruct their circuits within three months, as several of the spans of their wires are reported to be dangerous.

St. Thomas, Charterhouse, Schools.—The Clothworkers' Company valuable scholarship of £130 and five years' free training at the City Guilds and Central Institution (Technical Institute), at South Kensington, awarded for proficiency in English, Elementary Mathematics, Drawing, Physics (including Chemistry and Mechanics), has been taken by Philip Sageman, aged 14 years. For several consecutive years this prize has been taken by a pupil of the above schools.

Kalender fur Elektrotechniker.—The 1890 edition of the German Munro and Jamieson, as it may well be termed, is as crowded with electro-technical information as ever, the pocket-book having this year attained the respectable size of 284 pages of small print. The section on tests extends over 50 pages, while that on dynamos, their construction and testing, covers 30 pages. Other sections are devoted to electric lighting, the electric transmission of power, telegraphy, telephony, and electro-chemistry.

St. Pancras.—At a special meeting of the St. Pancras Vestry on Wednesday afternoon, it was resolved by 38 votes to 16 to obtain plans, specifications, and tenders for the supply of electricity for the purposes of light and motive power for 10,000 incandescent lights of 16-candle power each, and 90 arc lights. It was also resolved to employ Prof. Robinson to prepare the necessary plans, &c., and to call in, if necessary, Dr. Hopkinson as consultant. Mr. T. B. Westacott stated that the estimated cost of the installation was £60,000.

The Electrical Standardising, Testing, and Training Institution.—From our advertising columns it will be seen that a new institution has been formed, with Mr. Robert Hammond for founder and Mr. Hugh E. Harrison as principal, for undertaking the work of standardising instruments, testing apparatus and plant, and training electrical engineers, having electrical and engineering laboratories, equipped with modern measuring instruments and testing apparatus. Further information can be obtained of Mr. P. A. Latham, at the offices of the Institution, 15, St. Helen's-place, London, E.C.

"Electrical Industries."—The first number of *Electrical Industries*, which is the latest addition to the American electrical press, is entirely devoted to articles of a practical character. A distinguishing feature of this journal are the four directories which it is proposed to publish, corrected up to date, with every issue. These directories comprise (i.) A Directory of Electrical Manufacturers, (ii.) A Directory of Electric Light Stations, (iii.) A Directory of Electric Railways, (iv.) A Directory of Electrical Associations. *Electrical Industries*, which is published at Chicago, will appear monthly.

Electric Shot-Hoists.—The electrical ammunition hoist of Lieut. Bradley A. Fiske, now in operation on board the U.S. man-of-war "Atlanta," is reported to be giving satisfaction. The apparatus is called into play on all general quarters' calls, and hoists projectiles weighing 250lb. from the bottom of the hatch to the gun deck in ten seconds. In no instance has the hoist been taken down or given the slightest trouble. A great many naval officers were opposed to the apparatus on its introduction, but now nothing but praise is heard of it. The hoist has been put aboard the flagship "Chicago," and will, it is anticipated, be supplied to all the new ships.

The Vienna-Budapest Trunk Wire.—The telephone line between Vienna and Budapest was opened on Saturday afternoon. The first trials were satisfactory. The sound is conveyed with remarkable distinctness, every syllable uttered being so clear that the speaker may be recognised by his voice. Three wires have been put up, and it was found that two conversations might take place at the same time, but that the simultaneous use of the third wire unfavourably affected the transmission of sound on the two others. The Austrian section of the line is run at some distance from the railway and telegraph wires, but the Hungarian portion of the line is laid along the railway.

Postal Telegraph Revenue.—The revenue returns for the quarter ended December 31, 1889, show an increase in the gross receipts from the telegraph service of £75,000, as compared with the corresponding quarter of 1888. On a comparison of the annual periods ending December, 1888, and December, 1889, the increase during the latter amounts to £215,000. Details for the four quarters of the two years are as follows :—

	Mar. 31.	June 30.	Sept. 30.	Dec. 31.	Total.
1889...	£520,000	£525,000	£620,000	£590,000	£2,255,000
1888...	480,000	480,000	565,000	515,000	2,040,000
Inc.	£40,000	£45,000	£55,000	£75,000	£215,000

Electrolytic Preparation of Zinc and Tin.—Mr. Burghardt has recently devised a method of preparing zinc or tin by electrolysing a solution of an alkaline zincate or stannate. Whichever material is dealt with, it is necessary to first remove, by roasting, any sulphur, antimony, or arsenic that may be contained in the mineral. Thus refined it is converted into oxide, in which state it readily dissolves in a bath of melted caustic potash. The above two operations can be combined by pouring into the alkaline bath the refined mineral in a finely powdered state and adding powdered charcoal. On cooling, the mixture is dissolved with boiling water, and the solution is submitted to electrolysis.

Photographing Falling Water.—According to the *British Journal of Photography*, Herr E. Cohen, of Amsterdam, has recently succeeded in obtaining some interesting photographs of falling streams of water. He employed a vessel from the bottom of which issued a column of water one centimetre thick. The apparatus was placed in a dark chamber and illu-

Digitized by Google

minated by sparks from a Rhumkorff coil in connection with a Leyden jar. The falling column of water had a velocity of 8·28 m. per second, while the period of illumination was reckoned by Cohen at about $\frac{1}{82800}$ of a second. The results turned out most successful—the elevations and depressions of the stream, as well as the separate drops, being clearly distinguishable.

Electric Signalling Apparatus on the Northern of France Railway.—On the Northern of France Railway a very efficient electric apparatus is in use as a connection with the distant signals and the locomotives. On the road there is arranged a plate of considerable size; this is coupled with the distant signal in such a way that it rises when the signal is at danger, and is depressed when the disc shows "line clear." Upon the engine is a large and stiff wire brush, which sweeps over the surface of the plate when the latter is raised. An electric circuit passes from the terminal of a battery to the plate, thence through the brush to signalling apparatus on the engine, and from that to earth through the rails. The brush is not a delicate piece of apparatus, but a solid construction capable of sweeping snow off the plate, and of scraping its way through a coat of ice. The whole appliance is said to give very satisfactory results.

Wind Motors for Electrical Purposes.—The use of wind power for producing the electric light possesses the recommendation that it is cheap. A wind motor has been in successful operation for some time at the northernmost lighthouse at Cape de la Hague, where it drives two dynamos supplying accumulators. The windmill rests upon a timber framing, and transmits motion by means of a vertical shaft and two pairs of conical cog-wheels to a horizontal shaft. Pulleys are fixed to the latter, which drive the dynamos by means of belting. The windmill works automatically both during light winds and gales. This point has been obtained by employing a spherical regulator which acts by friction upon a shaft closing and opening the apertures in the wind wheel in such a manner that the surface exposed to the wind, according to its force, is enlarged or reduced. The dynamos are thrown in and out of gear automatically.

Transmission Plant at the Chevrant Paper Mills.—For the last three months the Chevrant Paper Mills at Domène (Isère) have possessed an electric power installation erected by M. Hillairet. The generator and receiver are over three miles apart. The 300 horse-power generator is driven direct by a turbine running at 240 revolutions. The water is conducted to the turbine in an iron pipe half a mile long, the head of water being equal to 230 feet. The receiver at the mills runs at 300 revolutions, and is capable of working up to 200 horse-power. The line is run overhead, and consists of a bare copper wire of 50 sq. mm. cross-section. The plant works day and night, and is only stopped twice within the 24 hours, for 20 minutes at a time. The average E.M.F. of the generator is 2,850 volts, and the average current is 70 amperes. The electrical efficiency of the installation is 83 per cent., the commercial efficiency, which has been very carefully determined, varies between 63 per cent. and 66 per cent.

The Paris Telephones.—M. Coulon recently appeared before the Budget Committee of the Chamber of Deputies and made a detailed statement with regard to the working of the telephone system by the State. Referring to Paris, M. Coulon stated that at present 7,000 subscribers were served by 12 exchanges, and the multiplicity of exchanges naturally resulted in considerable delay in making connections. The Paris staff was moreover insufficient and ill-disciplined, and the material handed over to the State by the Société Générale des Téléphones was worn out. M. Coulon asked for the sum of 500,000fr. in order to remedy urgent defects without delay. He proposes ultimately to reorganise and improve the entire system, by concentrating all the wires in one central exchange, by extending the telephone to the suburbs, and by erecting a trunk line between London and Paris. The necessary money will be obtained by deducting 1,000,000fr. from the 2½ millions annual profit at present made by the State. M. Coulon estimates that in ten years time the gross receipts from the telephone service will amount to 15,000,000fr., the net profits being at least 7½ millions. M. Coulon also reported that the number of new subscribers to the telephone system, which had fallen to 40 per month at the date of the transfer to the State, was 280 for October, 250 for November, and 180 for the first fortnight of December.

Electric Snow-Sweepers.—The following are some particulars of the electric snow-sweepers constructed for the West End Street Railway of Boston, and which recently proved so successful in operation. The car platform, which is framed of heavy oak timbers, is raised nearly 4ft. above the track and is about 6ft. wide by 20ft. long. This is supported by special heavy castings above a truck whose wheel base is 5ft. Upon the truck are mounted two 15 horse-power Thomson-Houston railway motors, one being geared to each axle exactly as in the ordinary mounting on a street car. These serve to propel the car only. The track brooms, which are cylindrical in shape, about 6ft. long and 30in. in diameter, are two in number and are mounted under the platform one at each end outside the truck, so that, in whichever direction the car is propelled, one broom will be in advance of the truck. The frame holding the broom is easily manipulated by levers upon the car platform. Upon the platform and about midway between its ends is mounted one 15 horse-power railway motor for driving the brooms. By means of a counter shaft and suitable clutches this motor may be made to drive either broom separately or both simultaneously, power being transmitted from the motor to the broom through a sprocket wheel and chain. The axis of the broom in changing from its highest to its lowest position is maintained at a constant distance from the counter shaft, thus retaining a constant amount of tension on the sprocket chain. Current is taken from the overhead wire by a trolley suitably mounted at the centre of the car. The whole of the machinery is enclosed, as far as possible, in snow tight, substantial cases, the platform machinery being especially well protected from possible injury by flying snow.

Electrical Activity in Canada.—Considerable energy is at present being shown in pushing electric lighting work in Canada. During the last year or two there has been a great development of electrical manufacturing in the Dominion, and as the demand is very brisk for apparatus, there is no reason to question the profitableness of these undertakings. One of the largest factories of the kind in Canada is that of the Royal Electric Company at Montreal, who bought the patent rights for Canada of the Thomson-Houston system, and who since 1884 have done a very large business. They have manufactured lamps and dynamos to the extent of about 7,000 arc-lamp capacity, and have plants running in Montreal, Ottawa, Quebec, Hamilton, London, Halifax, St. John, Charlottetown, St. Catharines, and many other places. In Montreal alone, where they began with 17 arc lamps in 1884, they now have 1,600 arc lights and 2,000 incandescents. The Edison Company have been at work for some time in Canada, and now have a large number of plants. Recently they reorganised their manufacturing business there, and now have matters on a good basis, being able to turn out a large quantity of material for which there is a steady sale. The Westinghouse Company have lately made a bid for Canadian business, and have already a large number of plants under way and in course of construction. The Western Electric Company have also sold plants in Canada; and a large number of small plants have been sold by the Ball and Reliance Companies. The Lahmeyer system also has its representatives in the Dominion, and the Brush Company have been at work there for some time, and have done remarkably well. One of the reasons for this electric lighting development is the number and availability of the water powers. A scheme which has just been put forward, and in which a large number of American capitalists of the North-West are actively interested, is the development of a grand water power at Port Arthur, in Ontario. Near that place is a river 350ft. wide, with a fall of 100ft., and it is proposed to build up a great manufacturing centre, such as Minneapolis, around these falls. Part of the power obtained is to be employed in a long-distance distribution of power electrically, and will be carried to a number of mines in the neighbourhood.

MAGNETISM IN IRON AND OTHER METALS.*

BY PROF. J. A. EWING, F.R.S.

II.

(*Continued from page 162.*)

§ 6. **Intensity of Magnetisation.**—We have seen that the magnetism of a magnetised bar may be described by reference to its ends, where the imaginary positive and negative magnetic substance is accumulated, the middle parts being inactive. From another point of view the magnetisation extends throughout the whole substance. We may think of every portion of the magnet as *polarised;* that is to say, every particle or elementary piece of the bar may be regarded as a separate magnet. Throughout the middle portion of the length these elementary pieces are grouped so that each pole of one touches the opposite pole of its next neighbour, and the result is that the middle portion of the bar shows no positive or negative magnetism; but at the ends the poles of the elementary pieces are no longer neutralised, and the poles of the pieces there become the poles of the bar. This is the modern view of the matter, and is in many ways an advance on the simple polar view. It is borne out by the fact, experimentally observed, that when a magnet is cut up into pieces, however small, each piece is a separate magnet.

§ 7. From this point of view we are to regard the magnetic state as existing continuously throughout the bar. If this state is uniform from end to end of a bar, the metal is said to be *uniformly magnetised.* If we could cut up such a bar by cross-sections into short lengths without disturbing the uniformity of the magnetisation, we should find every part to be a magnet with the same pole-strength as the original bar. If we could split it by longitudinal sections we should find the pole-strength of each part to be proportional to the area of cross-section in that part. In other words, if we could cut up the bar in any manner (always without altering the magnetic state of the metal) we should find that the pieces were separate magnets of which the moments were proportional to the volumes of the pieces. The magnetic moment of each piece will be the same fraction of the magnetic moment of the uncut bar that the volume of the piece is of the volume of the uncut bar. The magnetic state which existed throughout the bar before it was cut, and exists throughout each piece after cutting, may be specified if we state the *moment per cubic centimetre* of the metal. This quantity is called the *intensity of magnetisation*, and is usually denoted by I.

§ 8. **Relation of I to Pole-strength.**—Let M be the moment of a uniformly magnetised straight bar; let l be the length of the bar in centimetres, s its area of cross-section in square centimetres, and m its pole-strength.

Then $$M = m\,l.$$

The volume of the bar is $s\,l$; hence I, which is M divided by the volume, is $\frac{m\,l}{s\,l}$, or $\frac{m}{s}$.

We might, therefore, have defined I as the *pole-strength per square centimetre of sectional area.* It is useful to remember that I has also this meaning, but the essential idea implied in the phrase "intensity of magnetisation" is better conveyed by the definition of I given above. We are to think of I as the measure of a polarised state which has a true existence everywhere in the substance of the metal, though it manifests itself only at the ends, so far as external action is concerned.

§ 9. **Ring Magnet.**—The usefulness of this idea will be at once apparent if we consider what happens when a uniformly magnetised rod is bent round into a ring until the ends meet. There are now no poles: those that existed in the rod have met and have neutralised each other; there is now no magnetic moment, and the ideas of poles and moment will no longer serve as means of stating the magnetic state of the ring. But the ring is still magnetised: if we were to cut it in pieces we should find the pieces to be magnets. The magnetic state expressed by the quantity I still exists within the metal: there is a definite "intensity of magnetisation" throughout. If we were to cut a narrow gap through the ring we should find on one side of the gap a positive pole, and on the other side a negative pole, the strength of which would be $I\,s$.

§ 10. **Lines of Magnetisation.**—Suppose such a gap or crevasse to be cut, the number of lines of force which cross the gap is $4\pi I\,s$ (by § 4), and hence the magnetic force within the gap (which is the number of lines of force per square centimetre) is $4\pi I$; so far, that is to say, as the magnetic force there is due to the magnetism of the ring. Of course there may be additional magnetic force within the gap due to other magnets or to electric currents in the neighbourhood; but for the present we may confine our attention to the force that exists there on account of the magnetisation of the ring itself alone. The same lines $4\pi I\,s$ which cross the gap may be conceived as extending continuously round the ring through the substance of the metal. Each line forms a closed curve: a short part of it is in the gap, the greater part is in the metal. We may call the parts of the lines which lie within the metal *lines of magnetisation.* The name "lines of force," which is applicable to the lines in the gap, is inappropriate to those parts of the lines which lie within the metal, because the lines within the metal do not form a measure of the magnetic force there.

§ 11. **Lines of Magnetisation** (*continued*).—Fig. 4 illustrates the supposed case of a narrow gap or crevasse, A B, cut across the substance of a magnetised ring at any place in its circumference.

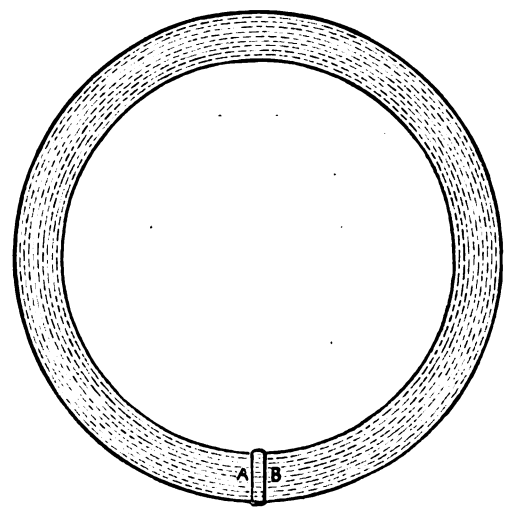

FIG. 4.

Within the metal we have the lines of magnetisation which are shown by dotted lines in the figure. The number of these, per square centimetre of cross-section, is $4\pi I$. These lines are continuous closed curves, and pass across the gap, forming lines of force there, which are shown by full lines in the figure. If we measure the magnetic force within the crevasse, we shall find it equal to this quantity, $4\pi I$, together with whatever other magnetic force may act there in consequence of electric currents or magnets in the neighbourhood. That part of the magnetic force within the crevasse which is represented by $4\pi I$, is directly due to the breach which we have made in the continuity of the magnetised ring. It may be regarded as existing there in consequence of the fact that lines of magnetisation within the metal are necessarily continuous with lines of force outside the metal.

Take another way of looking at the matter. We may think of this force within the crevasse A B as due to free magnetism on the surfaces A and B. When we cut the crevasse in the magnetised ring, we bring into existence a positive pole which is distributed over the surface at A, and a negative pole which is distributed over the surface at B. The strength of each of these poles is $I\,s$, and the surface-density of free magnetism—that is to say, the amount of free magnetism per square centimetre of surface—is I. By a well-known proposition in the theory of attraction, a plate on which the surface-density is I

* All rights are reserved.

Digitized by Google

attracts a unit particle placed close to it with a force equal to $2\pi I$ (except near the edge, where the force is less). Let a unit positive magnetic pole, then, be placed in the crevasse. The plate of free magnetism on A repels it with the force $2\pi I$; the plate of free magnetism on B attracts it with an equal force. The whole force at a point in the crevasse, due to the magnetisation of the ring, is the joint force exerted by the two plates; in other words, it is $4\pi I$.

Suppose now that the uniformly magnetised magnetic ring is stretched out to form a straight bar. If we imagine a crevasse to be cut across it at any part of its length, we shall still find in the crevasse the lines $4\pi I$ per square centimetre due to the continuous magnetisation of the bar, in addition to whatever lines of force may exist there in consequence of electric circuits or free magnetism in the neighbourhood (excluding, of course, the free magnetism on the faces of the crevasse, to which the lines $4\pi I$ are directly due). The whole field within the imaginary crevasse may therefore be thought of as made up of two components, namely, (1) the lines of magnetisation, the number of which is $4\pi I$ per square centimetre; and (2) the magnetic force due to external causes, namely, that which is due to electric currents and free magnetism in the neighbourhood. Amongst the causes of this magnetic force is to be included the free magnetism at the ends of the bar itself, as well as the poles of any other magnets which may be near enough to produce any sensible effect.

(To be continued.)

THE MANWAREN ELECTRIC METER.

We illustrate below a recent type of meter which has just been brought out by Mr. Albert H. Manwaren, of Philadelphia. This meter consists essentially of a multipolar magnet, a number of armatures, and a registering device, the action of which is controlled by the position of the armatures. In addition there is an electrically-operated winding device for the registering mechanism. We take our account from the *Electrical World* of New York.

Referring to Fig. 1, A is a multipolar magnet operating a series of armatures supported by the outside row of posts, and the inner ends free to move in the vertical slots of the central ring. The inner posts or cores are provided with a screw or thread for adjustment, which is made by graduating the distance of the cores from the armatures according to the quantity of current traversing the coils. Suppose, for instance, that the adjustment is made for lamps of 8 candle-power, then the current of one 8 candle-power lamp will raise the first armature, and by adding one more lamp of the same power the second armature is raised, and so on up to the capacity of the meter. Now, if one lamp of 8 candle-power and one of 16 candle-power be used, three armatures will be attracted; and if one lamp of 32 candle-power be added four more armatures will be raised, making seven armatures raised in the path of the registering trip, which registers the same as if seven lamps of 8 candle-power were burning. In Fig. 1 also the clockwork is shown having a hollow shaft supporting an arm at the lower end carrying the registering trip, which is rotated by the clockwork. The trip passing in under the end of the armatures that are up in its path, is depressed at the outer end, and the inner end raises the rod, which is free to move in the hollow shaft. The rod is connected to the movable plate supporting two pawls (push and pull), which is raised one tooth of the gear wheel and allowed to drop of its own weight as soon as the trip has passed the armature acted upon. The trip or lever is rotated by the clockwork once around in six minutes, thus making a new register of the exact number of lamps burning every six minutes. Each indication of the hand or pointer is equal to one lamp of 8 candle-power burning six minutes, or whatever candle-power is used for a standard and the meter is adjusted to. On one end of the rotating arm is a treadwheel, used to force all the armatures down in advance of the trip, and only those adjusted to the quantity of current flowing through the coils are attracted again.

In Fig. 1 H represents an end view of the automatic winding device, better shown in Fig. 2. This is a very simple arrangement, composed of two solenoid magnets, with one-half the core of each made of non-magnetic material. The yoke is used to support the rack, which is geared to the winding shaft of the clock. When the circuit is closed by means of the contact rod, the cores are drawn into the magnets, and in so doing the rack bar

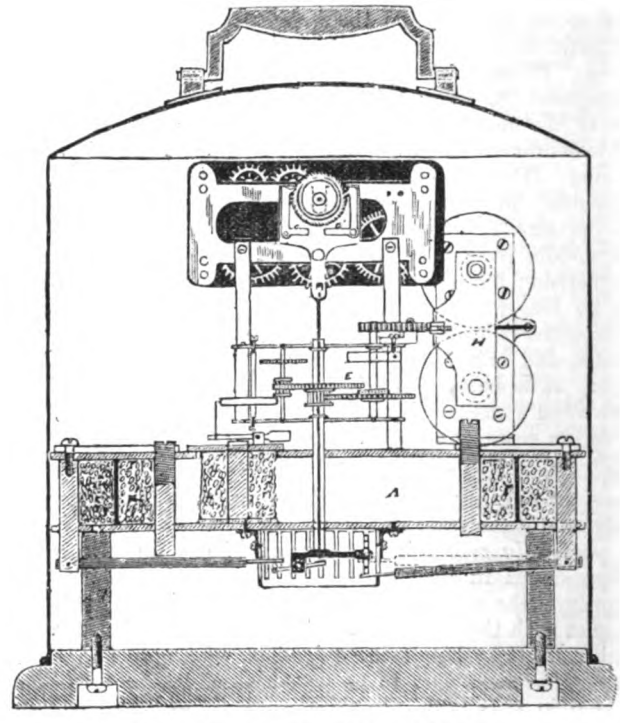

Fig. 1.—Section of the Manwaren Meter.

acts on the gearing and winds the spring. When the core has moved its full length a stud on the yoke pushes the contact rod away from the contact plates and opens the circuit. The spring now operates on the clock mechanism, and the rack bar is

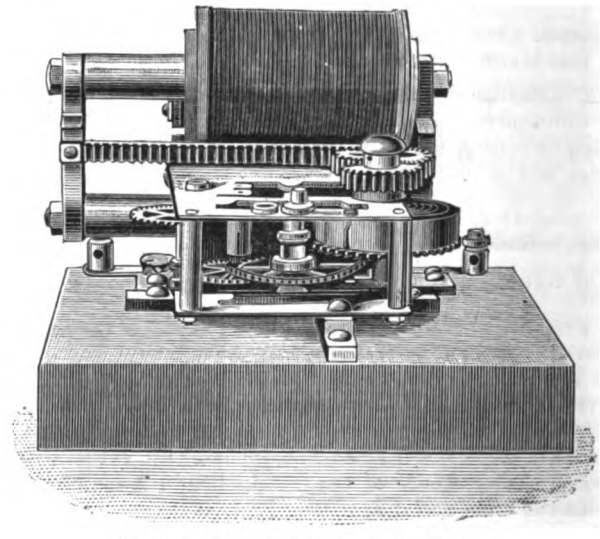

Fig. 2.—Manwaren Meter, winding device.

slowly moved to the length of its travel. At this point a stud, projecting from the rear end of the yoke, moves the rod in contact with the plates, closing the circuit, and causing a prompt back movement to wind the spring as before; this occurs every 20 minutes, and is entirely automatic in its action.

The arrangement for stopping the clock when there is no current being used is shown in Fig. 1. It consists simply of a small magnet connected in series in the lighting circuit, operating an armature which acts upon the balance-wheel; the

Digitized by Google

clock is started automatically by the movement of the armature when it is attracted again.

The meter is small (*see* Fig. 3) and is not limited in construction to any particular number of lights. A 25-light meter is 7in. in diameter and 8in. high, weighing 10lb.; a 100-light meter is 12in. in diameter and 10in. high; while a 200-light meter is the same diameter and 2in. higher. The large meters are constructed with several compound magnets, each having a set of armatures and a trip with one magnet placed above the other and one clockwork with the hollow shaft extending through all the different coils; this revolves all the different trips, which are set one rotation in advance of the other, so that only one trip is registering at a time. By this method a

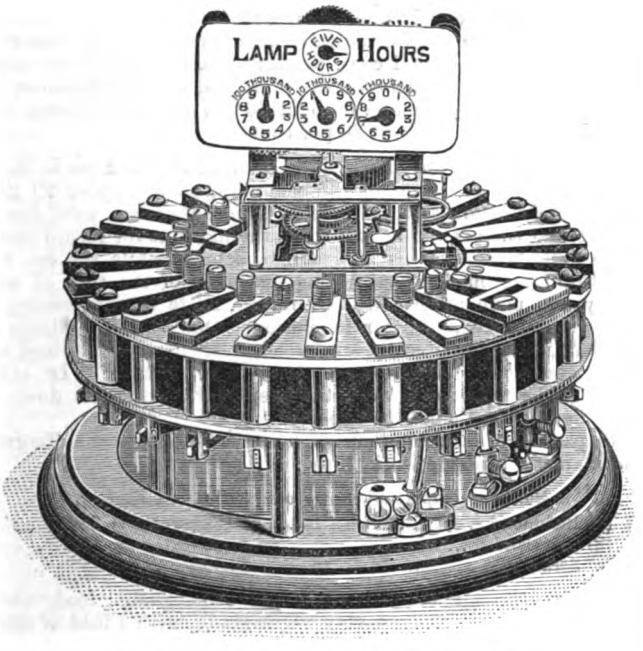

FIG. 3.—Manwaren Meter with case removed.

500-light meter composed of five 100-light coils placed one above the other, as mentioned above, is 12in. in diameter and 15in. high, making it convenient for transportation and requiring but a small space.

PRACTICAL POINTS IN ELECTRIC CAR SERVICE.*

BY O. T. CROSBY.

The following statement of facts results from observations made by Messrs. J. H. Vail, C. L. Edgar, Wm. Habirshaw, and myself, in the month of May, 1889. The number of individual readings taken was too great to permit repetition here. The system of observation was this:—Volt and ampere readings were taken at 30-second intervals, the instruments being placed on a car in each of the three cities—Richmond, Va.; Cleveland, O.; and Scranton, Pa. Notes as to passengers carried, stops made, &c., were taken on the car. Averages for long periods were taken from records kindly furnished by the railway companies in Richmond and Cleveland. On the three lines, which were carefully examined, the motors used were those of the Sprague Company's first type, save in the case of one car in Cleveland, which was run by motors of the Sprague Company's second type. The dynamos were of the Edison type. We obtained much interesting information by inquiring at the central station of the Eckington and Soldiers' Home Railway, Washington, D. C. This road has motors and dynamos of the Thomson-Houston Company. The facts given concerning this road are to be understood as not authenticated by instrumental checking. While the observations from which conclusions will be here drawn are now, perhaps, the most detailed and extensive of their kind, I hope many such will soon be on record, giving final values to certain important constants. More nearly than anything else, I believe that the car-mile is the unit of earning capacity, a certain population per mile being assumed. Hence the prominence of that unit below. The unit car may be taken as the regular 16ft. car. In Washington double-deckers constitute part of the equipment and appear very attractive.

* From the *Electrical World* of New York.

Coal Consumption.—We yet lack any accurate scale showing values of different coals as heat producers. Taking things as we found them:—

In Washington, soft coal cost per ton	$2.90
In Richmond „ „ „	3.00
In Cleveland „ „ „ (slack).....	1.25
In Scranton, culm coal (from adjacent pile), cost per ton ...	0.10

The coal consumption per car mile in these cities was as follows:—

In Washington, coal in lbs. per car mile ..... $\frac{2,800}{550} = 5{\cdot}0$lbs.

In Richmondco, mplicated by supply of light and power from same boilers.

In Cleveland, coal in lbs. per car mile ..... $\frac{10,000}{1,270} = 8{\cdot}0$ „

In Scranton, coal in lbs. per car mile..... $\frac{7,000}{1,200} = 5{\cdot}6$ „

The car-mileage per day of entire service in Washington, cannot be considered accurate; it was made up from the "say-so" of station *employés*, not referring to written records. Its error is probably not greater than 10 per cent.

Cost of Coal per Car Mile.

In Washington..... $\frac{2{\cdot}90 \times 5}{2,000} = 0{\cdot}72$ cent.

„ Cleveland..... $\frac{1{\cdot}25 \times 8}{2,000} = 0{\cdot}50$ „

„ Scratton ..... $\frac{0{\cdot}10 \times 5{\cdot}6}{2,000} = 0{\cdot}028$ „

Attendance.—In this I include only the attendance necessary for producing and delivering power, and nothing for conductors and drivers. Engineers, firemen, motor cleaners, linemen, and a part of general superintendence constitute this item.

Cost per Car Mile.

In Washington	2·5 cents.
„ Richmond, complicated as above.	
„ Cleveland	2·0 „
„ Scranton	2·0 „

Oil, Waste, Water, &c.—No great error will be made in putting this at 0·2 cent per mile at all points.

Interest, Insurance, Depreciation, and Taxes on Real Estate per Car Mile.—The value of real estate in the plants visited was not readily attainable. It was in no case used to its maximum capacity, and values per horse-power of total capacity varied very much. So, also, as to tax rate. The figures I will use must be understood as not founded on authentic data, but on fair approximation. The value of real estate for plant making 1,000 car miles per day is taken at $15,000; interest at 5 per cent.; depreciation at 2 per cent.; insurance and taxes at 2 per cent.; total, 9 per cent.

Applying this to $15,000 and dividing by $365 \times 1,000$, we obtain 0·37 cent per car mile.

Machinery and Line.—The cost of maintenance of the electrical machinery of a street railway has been the subject of much inquiry. The "extreme youth" of the art offers sufficient explanation of the vagaries shown by this element of cost. It has sometimes been riotous, like a boy out of school; sometimes quiet, like a boy after a flogging. At this date, maintenance on any road installed by one of the few well-known companies in the business will show a much more modest front than it did even six months ago. If we should take periods of six months on the roads in question they would, doubtless, all show great fluctuations in the depreciation figure. When, therefore, I take 5 per cent. per year on the whole electrical equipment, dynamos, motors, and line, I am giving expression to an opinion founded on many and varied happenings constituting quite a thorough practical experience in the work. Further, I must say that we will understand depreciation values one year from to-day much better than we do now. My 5 per cent. is "subject to change without notice," though guaranties very near this figure can now be had from reliable companies. Include in the plant on which 5 per cent. maintenance is to be calculated, the boilers and engines, and this percentage becomes still safer. It may be remembered that dynamo maintenance is known to be less than 5 per cent.; line maintenance by care can be kept inside that figure; hence, even if motor maintenance exceed that 5 per cent. our average remains nearly correct.

The total cost of steam and electric machinery and line equipment sufficient to perform a service of 1,000 car miles per day is an element as variable as the cost of real estate. As yet, also, we often find a capacity in excess of actual service. The use of iron

Digitized by Google

poles, instead of wood, will add from $800 to $1,600 to the cost of each mile of road.

In the systems here treated, the numbers of car miles per day made on each mile of line work are pretty closely as follows :—

Washington ...	200
Richmond	140
Cleveland (all double track)	400
Scranton	130

Differences in the proportions of single and double track and actual traffic demands largely affect such figures. The cost per mile of overhead work for various sets of conditions is now quite regular; but variation in the condition is considerable. Thus, nature of soil, kind of pavement, kind of rail, distance from station, number and size of cars per mile, grades, volume of traffic, number of trees on line, kind of pole, general finish of line, local price of labour, freight charges—all these enter. Again, I will here use probable values rather than actual costs of the above lines, on one of which especially a considerable expenditure was made for that valuable but intangible commodity—experience. I will, therefore, assume :

Average cost per mile of Richmond and Scranton type (wooden poles, lines principally single track)	$1,500
Average cost per mile, Cleveland type (double track, iron poles)	3,500
Average cost per mile, Washington type (centre pole of iron, principally double track)	2,700

These investments may be considered as sufficient to support more than the car mileages above given, but average traffic may not demand more. The investment for motors per car mile is now generally larger than it need be if traffic were everywhere heavy enough to demand double-car service (one motor car, one tow car). The equipment is frequently sufficiently powerful to do towing service when no such service is required. This figure also varies, in case of single car service, with what the owners choose to get out of their plant. Thus, in the points visited, average car miles per day for each motor car in service were :

In Cleveland, regular car mileage	90	miles per day.
„ Washington (approximate)	80	„ „
„ Richmond	60	„ „
„ Scranton	80	„ „
„ Cleveland	80	„ „

Since the date of inspection, the car mileage per day per car has increased greatly in Cleveland, and, I think, in Washington also.

The cost of motor equipments per car may now be taken at about $2,500. The dynamo capacity required to drive each car will generally be found to be from 7·5 to 10 horse-power. When the number of cars is considerable, the lower figure will apply to even the hours of heaviest traffic, but the desire to have a margin on dynamo capacity, thus permitting some increase in number of cars without increase of station plant, usually operates to give the larger figure, and often a higher one still. Actual readings, extending over long periods, showed a maximum of 7·5 horse-power per car, called for in Cleveland and Richmond, from 16 to 20 cars being on the line. The "say-so" of station *employés* in Washington and Scranton indicated about the same figure.

We may, therefore, assume 10 horse-power of dynamo capacity as installed for each car on the line. Save in very small units, the cost, covering spare parts and all station equipment, may be taken at $45 per horse-power.

The cost of engines and boilers is very near the same figure per horse-power, and we may assume 11 horse-power installed for every car in service. We may now sum up as to machinery and line work. Interest will be taken as before at 5 per cent. ; maintenance, as explained, at 5 per cent. ; taxes and insurance at 2 per cent. ; total, 12 per cent.

Then the cost per car mile =

$$\frac{\text{Cost one mile of line} \times 0{\cdot}12}{365 \times \text{car miles per mile}}, \text{ plus}$$

$$\frac{\text{Cost one car equipment} \times 0{\cdot}12}{365 \times \text{daily mileage per car}}, \text{ plus}$$

$$\frac{\text{Cost 10 H.p. dynamo} \times 0{\cdot}12}{365 \times \text{daily mileage per car}}, \text{ plus}$$

$$\frac{\text{Cost 11 H.p. steam plant} \times 0{\cdot}12}{365 \times \text{daily mileage per car}}$$

Applying the figures above given, we have for—

(1)	Washington, per car mile	1·8	cents.
(2)	Richmond „ „	2·20	„
(3)	Cleveland „ „	1·60	„
(4)	Scranton „ „	1·80	„
	Total	7·40	cents.
	Average	1·85	cents.

In (3), above, the large number of car miles per mile of line, and good figure for car mileage per car, bring the total down, in spite of an expensive line. Bringing all the items of cost per car mile together, we have, for motive power :

	Coal.	Attendance.	Real estate.	Machinery and line.	Oil and waste.	Total.
Washington ...	0·72	2·5	0·33	1·8	0·2	5·55
Richmond	0·72 (?)	2·5 (?)	0·33	2·25	0·2	6·00
Cleveland	0·50	2·0	0·33	1·68	0·2	4·71
Scranton	0·028	2·0	0·33	1·83	0·2	4·18
Average	...	...	...	...	...	5·09

The figures for Richmond marked (?) were not attainable. Coal and labour being of nearly the same values as in Washington, equality in these items has been assumed.

Interest on investment constitutes about one-fourth to one-fifth of the whole, *i.e.*, about 1 cent. per car mile, or, say, 20 per cent. of the total. Coal (except in the abnormal case of Scranton) is about 12 per cent., attendance about 40 per cent., machinery and line (without interest) about 20 per cent.

Effect of Grade.—Out of a total of 120 readings on a car in Richmond, going over a line of heavy grades, there appear 29 zero readings for current, and of these not more than six were due to the fact that the car was at rest when the moment for record came. Let us take, however, only 20 readings as made while the car was in motion ; that means, that during one-sixth of the time of run, gravity and momentum effects combined, made it unnecessary to use current to keep the car in motion. Out of 120 readings in Cleveland, over a practically level road, only 15 zero readings are found, and nearly all these were noted as "stops." In other words, grades work both ways, and keep average currents down to better figures than might be expected.

Comparison of maximum efforts, however, indicates the disagreeable character of grade work, thus :

Maximum supply of energy observed at one reading.

(1) Richmond	19,225	watts =	25·6 H.p.
(2) Cleveland	11,500	„ =	15·0 „
(3) Scranton	14,400	„ =	19·2 „

Reading (1), was taken on a 9 per cent. grade ; load, about 8,500lbs. ; reading (2), on a very slight grade, with a load of about 9,800lbs. ; reading (3), on about a 7 per cent. grade, load about 8,800lbs. On other occasions in Richmond I have seen, with extravagant loads, readings nearly 50 per cent. greater than the 25·6 above.

An important relation to be observed, as facilitating calculations, is the relation between car mile and horse-power hour. This relation was found to be :

From special test in Richmond	1	car mile =	1·01 H.p.
„ „ Cleveland	1	„ =	0·67 „
„ „ Scranton	1	„ =	0·94 „
From averages of several days in Richmond	1	„ =	1·18 „
„ „ „ Cleveland	1	„ =	0·90 „
Average			·94 H.p.

The loads in the special tests were ordinarily from four passengers to 24. In these figures the beneficial effect of small grades is seen. It is probable that the average number of passengers carried per car mile is in Cleveland (type of light grades) greater than in Scranton or Richmond (type of heavy grades), otherwise the difference would be greater between the heavy grade and the light grade roads.

It is to be noted that the horse-power here considered is that delivered to the cars. To learn what the same relation is when carried to the power house, we must next learn of the line efficiency. Taking figures of special tests, this is as follows :

In Richmond	88	per cent. (1)
„ Cleveland	94·4	„ (2)
„ Scranton	88	„ (3)

These percentages will not, of course, be maintained at hours of heaviest traffic. In (1) and (3) a number of track connections were broken, causing considerably more than necessary loss with the copper actually on the line. Whatever the loss may be in these three roads, we all know that the loss may be made what we please. Let us take it at 10 per cent. It may then be said, closely enough for anything less than very accurate calculations, that on average roads one electrical horse-power hour in the station will produce one car mile of service on the line.

Nearly the same value for this relation may be deduced from figures published by Dr. Louis Bell, taken from practice of the Lafayette, Ind., electric railway (*The Electrician*, July 5 and 12, 1889). He says that 16·1lb. of coal were required to produce one electrical horse-power hour. He says that six cars are in use,

Digitized by Google

making from 35 to 40 miles per day. We may assume then about 230 car miles per day.

Total coal consumption for the day was given as 4,500lb.;

$$\frac{4500}{230} = 19{\cdot}5.$$

Hence, one car mile $= \frac{19{\cdot}5}{16{\cdot}1}$, or 1·22 electrical horse-power hours.

The figure for coal is very high as compared with practice in a great majority of electrical stations, for either light or power. Coal per indicated horse-power hour is given by Dr. Bell as 7·3. This is high enough, but the jump to 16lb. per electrical horse-power hour shows poor steam and shafting service, or error in calculation. Another relation calculated, that between maximum two-hour supply of energy and average supply of energy, may become of importance, especially in the case of purchase of power by meter, the seller wanting to know beforehand how much current he can *sell* from a certain plant for car service. The plant must have *normal* capacity to supply the maximum effort continuing for a reasonable time, say one hour, while it may be relied on to "spurt" for an extravagant, but very short demand.

I found that in Richmond, with about 21 cars out, readings, extending through several days, showed a current of 220 amperes as flowing continuously for one hour, while the average of same readings, reduced to 24 hours per day, equalled 110 amperes, or 50 per cent. of the one-hour maximum. In Cleveland, corresponding figures were respectively 173 amperes and 66 amperes, *i.e.*, 38·3 per cent.; 16 cars being in service. Taking the mean of 50 and 38, that is 44, we may say that, on average roads, only 44 per cent. of the 24-hour capacity of the central station plant will actually be used on the cars, the plant being such as can easily handle maximum loads of one hour duration.

Miscellaneous Facts.—In Cleveland schedule speed is nine miles per hour. We made ten miles an hour on the observation trips, including stops for a number of passengers, the length of route being 3·3 miles. In Scranton and Richmond schedule time is about six miles per hour.

Special tests limited to the exact time of a run, and made by daylight, do not measure all the power really consumed in car service. Lights at the station and on the cars, field circuits of shunt dynamos, movements of cars in yards, leakage and drop on the line; all these make their demand on the engines. Most of these additions are independent of grade; hence, as shown above, average car mileage per horse-power hour in the station, and from bus-line ammeter readings, will be found more uniform, as between different roads, than the trip determinations on the cars. Thus, from

Special Tests.

	Horse-power Hours per Car Mile
Cleveland	·67
Richmond	1·05 = 50 per cent. greater than ·67
Scranton	0·94 = 42 per cent. greater than ·67

From Station Readings.

Cleveland	0·9
Richmond	1·18 = 31 per cent. greater than 0·9

The average expenditure of energy on cars, as shown in the special tests was:

	Watts.	H.P.	Average Load.	Total Rise.	Average Speed.
Richmond	4,833	6·5	8,500	55 feet.	6, one way
Cleveland	4,986	6·6	9,500	0 „	9, round trip
Scranton	5,587	7·4	9,500	100 (?) „	5·7, one way
„	3,400	4·5	8,200	100 (?) „	6·0, one way
„	4,494	6·0	8,800	0 „	5·85, round trip

Starting currents were generally 18 to 20 amperes, with about 460 volts at car. On grades, starting currents were 25 amperes. The voltage at certain points was found as low as 325, due to bad ground connection, station voltage being about 475. At many points on the lines in Cleveland and Scranton 500 volts were recorded, voltage at stations being 505 to 525.

It is to be remembered that in all individual tests, equipped with moters of any kind now used, the handling of the variable resistance, whether internal, as in the commutated field of the Sprague Company's motor, or external, as in the Thomson-Houston motor, may produce results less favourable than the best possible results. An intelligent motor-man can save coal just as an intelligent driver of horses saves hay or horseflesh. The results given above involve the personal equations of average drivers.

PROVISIONAL ORDERS.

METROPOLIS.

Name of Applicant.	Title of Order.	Area covered by Order.
The House-to-House Electric Light Supply Company.	House-to-House Electric Light Supply Order.	Two areas within the parish of Kensington, St. Mary Abbot.
The Kensington and Knightsbridge Electric Lighting Company.	Kensington and Knightsbridge Electric Lighting Order.	A portion of the Parish of Kensington, St. Mary Abbot, and the detached portion ef the Parish of St. Margaret, Westminster.
The London Electric Supply Corporation.	London Electric Supply Corporation Electric Lighting Order.	Parishes of: St. James, Westminster. St. George, Hanover-sq. Chelsea (except the detached portion). Rotherhithe. Clerkenwell. Bermondsey. St. Mary, Newington. Lambeth (portion north of Westminster Bridge-road). St. Martin-in-the-Fields (portion west of St. Martin's-lane and south of the Strand). The united Parishes of St. Margaret and St. John-the-Evangelist, Westminster (the portion north of Victoria-street, Parliament-square, and Bridge-street). The Districts of the following Boards of Works:—Greenwich District, St. Olave's District, St. Saviour's District.
The Metropolitan Electric Supply Company.	Metropolitan Electric Supply Company (Mid-London) Lighting Order.	The Districts of the following Boards of Works:— St. Giles' District. Holborn District. Strand District.
	Metropolitan Electric Supply Company (West London) Lighting Order.	The Parish of St. Marylebone.
The Notting Hill Electric Lighting Company.	Notting Hill Electric Lighting Order.	A portion of the Parish of Kensington, St. Mary Abbot.
The Electricity Supply Corporation.	St. Martin Electric Lighting Order.	The Parish of St. Martin-in-the-Fields.
The Chelsea Electricity Supply Company.	South Kensington Electric Lighting Order.	A portion of the Parish of Kensington, St. Mary Abbot.
The Westminster Electric Supply Corporation.	Westminster Electric Lighting Order.	The Parish of St. George, Hanover-square, and the portion of the United Parishes of St. Margaret and St. John the Evangelist, Westminster, lying to the South of the line of the Metropolitan District Railway.

PROVINCES.

Messrs. Chamberlain and Hookham.	Birmingham Electric Light and Power Order.	A central district of the town of Birmingham.
The Liverpool Electric Supply Co.	Liverpool Electric Lighting Order.	A portion of the City of Liverpool.
The Corporation of Swansea.	Swansea Electric Lighting Order.	Swansea.

LICENCES.

METROPOLIS.

Name of Applicant.	Name of District.
*Kensington Court Electric Lighting Company.	Part of the Parish of Kensington, St. Mary Abbot.

* This Licence was superseded by the Kensington and Knightsbridge Electric Lighting Order.

PROVINCES.

Corporation of Dublin (Public purposes only).	A portion of the City of Dublin.
Wimbledon Local Board.	Wimbledon.

ELECTRIC LIGHTING NOTICES FOR 1890.

The following is a corrected list of the applications for Provisional Orders deposited with the Board of Trade on or before the 21st of December, 1889. The number of applications, it will be noticed, has been reduced from a total of 179 (see *The Electrician*, December 6th) to 161. Five of the 18 applicants who have dropped their Orders are Local Authorities, and we may expect to see this figure further increased as time goes on. The remaining 13 are mainly companies who have decided not to proceed with their applications in competition with the Local Authorities:—

THE METROPOLIS.

The METROPOLITAN ELECTRIC SUPPLY COMPANY (LIMITED), of Winchester House, Old Broad-street, have applied for two Orders—(1) for the City of London, the parishes of Paddington, St. John, Hampstead, St. Pancras, St. Mary, Lambeth, and so much of the parishes of Clapham and Streatham as is included in the district of the Wandsworth District Board of Works; and (2) for the City of London and its liberties.

The LONDON ELECTRIC SUPPLY CORPORATION (LIMITED), of 3, Adelphi-terrace, Strand, apply for two Orders—(1) for the City of London and its liberties; and (2) for St. Pancras, Islington, Shoreditch, Paddington, Bethnal Green, St. Luke, Middlesex; St. George-in-the-East, Mile End, Hampstead, Hammersmith, Fulham, Whitechapel, Hackney, Limehouse, Poplar, Lambeth, Camberwell, and St. George-the-Martyr, Southwark; Wandsworth, Woolwich, Plumstead, Lewisham, West Ham, and East Ham.

The HOUSE-TO-HOUSE ELECTRIC LIGHT SUPPLY COMPANY (LIMITED), of 117, Bishopsgate-street, E.C., apply for eight Orders, authorising them to produce and supply electricity—(1) in the parish of Islington and the district of the Hornsey Local Board; (2) in the parishes of Fulham and Hammersmith; (3) in the parish of St. Pancras; (4) in the parish of Lambeth; (5) in the district of the Wandsworth Board of Works; (6) in the parish of Paddington; (7) in the districts of the Acton and the Ealing Local Boards; and (8) in Hampstead, Finchley, Hendon, and Willesden.

Application will also be made to the Board of Trade for Provisional Orders on behalf of the LAING, WHARTON, AND DOWN CONSTRUCTION SYNDICATE (LIMITED), of 82A, New Bond-street, W., with respect to the City of London and its liberties.

Messrs. A. AND S. GATTI apply for a Provisional Order to supply electricity for public and private purposes in a portion of the parish of St. Martin-in-the-Fields, and in a portion of the area of the Strand District Board of Works.

The ELECTRIC INSTALLATION AND MAINTENANCE COMPANY (LIMITED), of 4, Great Winchester-street, E.C., apply for a Provisional Order with respect to certain parts of the districts within the jurisdiction of the Lambeth Vestry, the Vestry of Camberwell, the Lewisham District Board of Works, the Beckenham Local Board, and the Croydon Corporation.

The SOUTH OF ENGLAND HOUSE-TO-HOUSE ELECTRICITY COMPANY, of 15, St. Helen's-place, E.C., apply for an Order with respect to Richmond, Mortlake, and Barnes.

Three Provisional Orders will be applied for by the BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED)—(1) for the City of London; (2) for the parishes of Hampstead, St. Leonard, Shoreditch; St. Pancras, St. James and St. John, Clerkenwell; St. Luke, Old-street, St. Marylebone, St. Mary, Islington; St. Matthew, Bethnal Green; and the districts of Whitechapel, Hackney, and Stoke Newington; and (3) for Hammersmith and Fulham.

Provisional Orders will also be applied for by the St. James and Pall Mall Electric Light Company (Limited), for the parish of St. James, Westminster; by Messrs. Renshaw, King, and Co., and by the City of Westminster Electrical Syndicate (Limited), for the united parishes of St. Margaret and St. John, Westminster; by the Westminster Electric Supply Corporation (Limited), for parts of the parishes of Paddington and St. Marylebone; by the Chelsea Electricity Supply Company for the parish of St. George, Hanover-square; and by the Kensington and Knightsbridge Electric Lighting Company (Limited), for that part of the united parishes of St. Margaret and St. John, Westminster, which is not included in the Kensington and Knightsbridge Electric Lighting Order, 1889, and for the parishes of Paddington, St. Marylebone, and St. George, Hanover-square.

PROVINCES.

Town, &c.	Name of Applicants.
Aberdare	Western House-to-House Electricity Company.
Aberdeen	The Corporation.
	Scottish House-to-House Electricity Company.
Accrington	The Corporation.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(To-night) FRIDAY, January 3rd.

LONDON INSTITUTION.

4 p.m. Lecture: "Soap Bubbles, and the Forces which Mould Them." By C. V. BOYS, F.R.S.

SATURDAY, January 4th.

ROYAL INSTITUTION.

3 p.m. Lecture: "Electricity." By Prof. A. W. RÜCKER, M.A.

MONDAY, January 6th.

LONDON INSTITUTION.

5 p.m. Lecture: "Egyptian and Assyrian Marbles in the British Museum." By LOUIS FAGAN.

TUESDAY, January 7th.

ROYAL INSTITUTION.

3 p.m. Lecture: "Electricity." By Prof. A. W. RÜCKER, M.A.

ROYAL VICTORIA HALL.

8:30 p.m. Lecture: "A Visit to the Chief Cities of Italy." By Rev. W. W. EDWARDS.

WEDNESDAY, January 8th.

CIVIL AND MECHANICAL ENGINEERS' SOCIETY.

7 p.m. Annual General Meeting. Paper to be read at the subsequent Ordinary Meeting:—"Notes on Prices for Labour and Materials in India." By H. H. PARKINSON, A.M.I.C.E.

SOCIETY OF ARTS.

7 p.m. Juvenile Lecture II.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read, "On the Variations of the Female Reproductive Organs, especially the Vestibule in Different Species of Uropoda." By A. D. MICHAEL.

THURSDAY, January 9th.

ROYAL INSTITUTION.

3 p.m. Lecture: "Electricity." By Prof. A. W. RÜCKER, M.A.

LONDON INSTITUTION.

6 p.m. Lecture: "Birth and Growth of Worlds." By A. H. GREEN, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary Meeting. Inaugural Address by the President, Dr. John Hopkinson, F.R.S.

FRIDAY, January 10th.

INSTITUTION OF CIVIL ENGINEERS.

7.30 p.m. Ordinary Meeting. Paper to be read, "The Irrigation Works on the Cauvery Delta." By Alfred Chatterton, B.Sc.

The Electrician.

Published every Friday. Price Fourpence; Post Free, Fourpence Halfpenny

Editorial, Publishing and Printing Offices:

No. 1, SALISBURY COURT, FLEET STREET, LONDON, E.C.

Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Communications to be addressed to "THE ELECTRICIAN," *1, Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN."

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails. Subscribers should receive their copies by the first post on Friday morning.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the United Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from the Publishing Offices as above.*

SPECIAL NOTICE.

Owing to the increase in the number of pages of "THE ELECTRICIAN," in order to partly cover the increased postage, we have been compelled to revise the rates for Foreign Subscriptions, which are now as follows:—

	3 months.	6 months.	12 months
	s. d.	s. d.	s. d.
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0
The rates for the United Kingdom remain as follows:—	5 0	10 0	19 6

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has the largest circulation of any English Electrical paper, and circulates all over the World.**

Particulars relating to Advertisements will be promptly forwarded on application to the office.

TRADE ADVERTISEMENTS *intended for the current issue must be handed in not later than First Post on Thursday morning.*

SMALL PREPAID ADVERTISEMENTS *(for Rates see page xiii.) are accepted up to 4:30 p.m. on Thursday.*

TECHNICAL PRINTING.

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY (LIMITED) *beg to inform Electricians, Electric Light Engineers, &c., that they make a specialty of Technical Printing, and have a Staff thoroughly acquainted with Electro-Technology. They can, therefore, promise Accuracy and Despatch in the Printing of Electrical Catalogues and Electro-Technical Literature generally.*

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK.

Royal 8vo.

Early in each year is issued "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK. *The* DIRECTORY *was established in 1883, and the 1889 Edition consisted of more than 600 pages of printed matter. The names and addresses of all persons engaged in the Electrical Industries may be relied upon as accurate. Useful Tables and Electrical Formulæ, and information specially compiled for this work are given, together with popularly-written Biographical Notices of the leading Electricians, Electrical Engineers, &c., accompanied in many cases by Portraits.*

The issue for 1890, which will be still further enlarged and improved, is in active preparation. New Names and Addresses, Corrections, Advertisements, &c., should be forwarded at once to the Publishing Office, **1,** *Salisbury-court, Fleet-street, London, E.C.*

CONTENTS OF THE CURRENT NUMBER.

OUR SUPPLEMENT.

With this Issue of "The Electrician" we present our Subscribers with a MAP showing the Metropolitan areas at present allotted to the various Electric Light Supply Companies.

Subscribers should receive this Supplement Gratis, and complaints of non-receipt should be at once addressed to "The Publisher."

"THE ELECTROTECHNISCHE-ZEITSCHRIFT" OF BERLIN.

In future the above journal (with which has been incorporated "The Centralblatt für Electrotechnik") will be issued weekly instead of fortnightly, the price remaining **£1** *per annum.*

"THE ELECTRICAL WORLD" OF NEW YORK.

"THE ELECTRICAL WORLD" OF NEW YORK *can be obtained from "THE ELECTRICIAN" Office, Salisbury-court, Fleet-street, London, E.C. The Rate of Subscription (payable in advance), is* **£1 1s.** *per annum. Single Copies* **price 6d. each; post free, 8d.**

"THE ELECTRICIAN" PRINTING AND PUBLISHING COMPANY, Ltd., *are Agents in Great Britain for both the above well-known journals, and particulars as to Advertisements will be supplied on application to "The Publisher," 1, Salisbury Court, Fleet Street, E.C.*

1889.

The year 1889 will long be memorable in the annals of electric lighting in England as one in which was witnessed an outburst of electrical activity, rivalling to some extent the great railway mania of 1846. In the early part of the year attention was mainly concentrated on the proceedings of the different supply companies who were competing for the honour and profit of illuminating the metropolis. The necessity of deciding upon some general principle by which they should be guided in allocating metropolitan areas, together with the great variety of systems proposed and the conflicting demands of the vestries, led the Board of Trade to set on foot an exhaustive inquiry into the applications of the various companies. This inquiry was opened at the Westminster Town Hall, on April 3rd, and extended over 18 days. It was ably conducted on behalf of the Board of Trade by Major Marindin, R.E., assisted by Major Cardew, R.E. The questions of high and low-tension, battery distribution, "districting" and "potential competition," were argued before the Inspector at considerable length, and amongst those examined were Lord Crawford, Sir William Thomson, Sir John Pender, Dr. Hopkinson, Prof. Forbes, and Mr. Ferranti. At the close of the inquiry,

Digitized by Google

Major Marindin announced that he would report without loss of time, and within ten days his report was in the hands of the Board of Trade. Amongst the many points of interest in this very able report, perhaps the most important was the recommendation that for the present, powers should not be given to more than two companies over the same area, and that only one of these should be an alternate-current transformer company. On July 16th the Bills embodying the metropolitan electric lighting schemes came before a Select Committee of the House of Commons, and on the last day of August they received the Royal assent, statutory powers being granted to the London Electric Supply Corporation, the Metropolitan Electric Supply Company, the House-to-House Electric Light Supply Company, the Chelsea Electricity Supply Company, the Kensington and Knightsbridge Electric Lighting Company, the Notting Hill Electric Lighting Company, the Westminster Electric Supply Corporation, and the Electricity Supply Corporation. As soon as their Orders had been confirmed by Parliament, the companies set to work without delay, and the condition of our main thoroughfares soon testified to the fact that the electric lighting of London was at last being seriously undertaken. The demand for current has been most encouraging, and in some instances it has more than kept pace with the supply. Although the districts allotted to the eight successful companies cover several square miles, a large portion of the metropolis, including the City, still remains untouched, and for this virgin territory there are at the present moment no less than fourteen applicants. In spite of the diversity of methods, and the novelty of many of the systems of underground mains, we have up to the present no serious hitch to record; and it may fairly be anticipated that the freedom from accident which has characterised the operations of the metropolitan companies will continue to attend them, so long as the work is carried out with due care and engineering skill.

Turning from London to the Provinces, there is little of note to record during the first half of the year. Towards the end of June, however, electric lighting notices were showered upon the provincial Local Authorities in all directions, nearly 400 notices being served. The attitude taken up by the provincial authorities was at first somewhat antagonistic, and there was a general cry that the lighting, if undertaken at all, should be in the hands of the ratepayers. As soon, however, as the cost of this heroic policy came to be counted, the authorities showed more disposition to allow private companies to carry out the work, under stringent conditions. A large number of Local Authorities, however, persisted in their determination to keep the supply of electricity in their own hands; and the applications of Local Authorities form nearly 30 per cent. of the total of 179 recently sent in to the Board of Trade. Only a small proportion of the applications by Local Authorities can, we think, be deemed genuine: already many of them have been dropped, having served the purpose of fending off private companies, and more will doubtless fall out of the race. Moreover, too much must not be expected even from those Local Authorities who go through with their applications, since many of them are owners of gasworks, and have plainly intimated their intention of preventing the electric light from injuring the ratepayers' gasworks property. A sufficient number of Orders will, however, no doubt be proceeded with to keep our manufacturing firms well employed during the next twelve months. The attitude of many of the provincial authorities towards electric lighting has certainly been ambiguous, but they have in most cases been prompt in coming to a decision one way or the other. As much cannot be said for the Commissioners of Sewers. The question of the electric lighting of the City has been before this body for more than two years, yet it is only within the last month that the Commissioners have been able to allot the western portion of the City to an electric lighting company. The central and eastern districts at the time of writing remain unallotted, though it is *hoped* that they will shortly be dealt with. Five companies are, however, applying for lighting powers within the City, so that it may be anticipated that this policy of delay will not much longer retard the introduction of the electric light into the heart of the metropolis.

Although three decisions affecting leading electrical patents were given during the year, no fresh litigation of importance has been commenced; and it is, we hope, not too much to expect that in future, with so much profitable work to be done, the litigious spirit will be less pronounced. Early in February the Court of Appeal reversed the decision of Mr. Justice Kay and sustained the Edison patent of November 10th, 1879. A month later, the Court of Appeal upheld the decision of Mr. Justice Kekewich invalidating the Gaulard-Gibbs transformer patent. Finally, in June, Lord Trayner, in the Court of Session, held that the Brush compound winding patent, No. 2,003 of 1878, was invalid. Perhaps the most satisfactory event in connection with this array of costly patent litigation was the compromise entered into between the Edison-Swan Company and the Brush Company, whereby an appeal to the House of Lords was avoided.

Activity in all branches of electrical industry, which has formed so marked a feature of the year, has naturally resulted in the formation of a large number of new and the amalgamation of several old companies. Space does not permit of more than a mention of the most important. At the beginning of the year a Company was formed, with a capital of £500,000, to work the Elmore copper depositing process, by which it is claimed that a copper of very high conductivity and great tensile strength is obtained. In June the Electrical Power Storage Company, Messrs. Elwell-Parker, and the Railway Electrical Contractors amalgamated under the name of the Electric Construction Corporation. This company owns the Sprague and the Julien patents for the United Kingdom, and may be expected to push electric traction in an energetic manner. In July an English Westinghouse Company was formed, with a capital of £600,000, and a few weeks later the Anglo-American Brush Corporation amalgamated with the Falcon Engine and Car Works Company and the Australasian Electric Light, Power, and Storage Company, the united companies taking the title of the Brush Electrical Engineering Company. The year 1889 has been especially fruitful in the commercial development of new applications of electricity. In support of this statement we need only mention the Webster electrical sewage process, which has now been for some time in successful operation at Crossness; the electric tanning process of MM. Worms and Balé; the electric welding process of Prof. Elihu Thomson, the great value of which was made widely known by the exhibit at the Paris Exhibition; and Mr. Langdon-Davies' phonopore, which was described in these columns in April last.

The first year of the existence under its new title of the Institution of Electrical Engineers opened with the President's memorable discourse on "Ether, Electricity, and Ponderable Matter." Subsequent Papers, though not, perhaps, so warmly discussed as those of the previous year, have been of great value, and the attendance at the meetings tends to increase more and more. Mr. Mordey's remarkable Paper on "Alternate Current Working," for which he received the "Institution" premium, gave rise to an interesting debate, as did Dr. Lodge's Paper on "Lightning, Lightning Conductors, and Lightning Protectors." The chief point of interest in Mr. Mordey's Paper lay in the formula-disturbing maxim put forward by him and supported by abundant experimental proof that if alternators are made, amongst other things, with

Digitized by Google

the least possible self-induction and the lowest practicable resistance, they will not only be the best alternators, but they will best run parallel. The Institution, moreover, marked the first year of its existence by a meeting in Paris and by a public dinner, at which Lord Salisbury and many other distinguished guests were present. Owing to the success of the dinner it has been decided to make it an annual event. In June a joint deputation from the Institution and the London Chamber of Commerce had an interview with Sir Michael Hicks-Beach, and pointed out the necessity for the establishment of a well-organised Government Standardising Laboratory, and at the present moment this important matter is under consideration by the Treasury.

Among the many events of an eventful year we must not omit to mention the meeting of the International Congress at Paris and of the British Association at Newcastle. The Paris Congress, although a distinct success as a social gathering of electrical workers from all over the world, was by no means of the same scientific importance as that of 1884. The opening meeting of the Congress was held on August 24th, M. Mascart being elected President, and Sir William Thomson Honorary President, and from that day until the close of the Congress on August 31st the various sections applied themselves assiduously to the work in hand. Several decisions with regard to electrical nomenclature were arrived at, the most important being the adoption of the name "quadrant" for the unit coefficient of induction, and of "resistance apparente" (subsequently converted into "impedance" by the Electrical Standards Committee of the British Association) for the ratio of the effective E.M.F. to the effective current. At the British Association, the electrical Papers were less interesting than those of the previous year; but in Section G there were several of great practical value. The Paris Exhibition, the Birmingham Exhibition, the opening of the first municipal central lighting station at Bradford, and the collapse early in the year of the French copper syndicate are all events worthy of notice. It is scarcely necessary to refer to the useful part played by the Electrical Section of the London Chamber of Commerce during the year, the concessions recently obtained from the Executive Committee of the Edinburgh Exhibition by the action of the committee of the Section being fresh in the minds of us all. During the year the number of central lighting stations at work in the United Kingdom has increased from 27 to 46, while electric traction has come into operation at Gravesend, Carstairs, and Barking.

As was to be anticipated, the various engineering and manufacturing firms have been very busy throughout the year, and there is every sign that the present prosperous condition of affairs will be maintained during the coming year, and to show this we cannot do better than give in brief some of the reports kindly furnished us by leading firms. Messrs. Immisch and Co. report a steadily increasing demand for electrical plant for lighting and transmission of power, both at home and abroad. During the year this firm has more than doubled the output of the preceding twelve months. Amongst the plants turned out by this firm are a 70 horse-power hauling plant, for St. John's Colliery, Normanton; a 30 horse-power pumping and hauling plant for Llanerch Pit, Pontypool; a 30 horse-power pumping plant for the Shale Mines at West Calder; a 35 horse-power pumping and winding plant for tin mines in Bohemia; a 40 horse-power fan driving plant for Bohemia, &c. In connection with the Electric Traction Company, Messrs. Immisch and Co., as chronicled in these columns, have been running self-contained tramcars on the North Metropolitan lines between Barking and Canning Town continuously for more than seven months At the end of November, when five cars were running, the horses were withdrawn, and the service depended entirely upon the electric cars. Each car makes on an average 60 miles per day, so that the possible car mileage per week is about 2,100. The total mileage yet made is about 40,000 miles. The cars have kept the schedule time within about 2 per cent. The engineers report that the Electrical Power Storage Company's plates are standing the rough usage much better than expected. Indeed, the chief difficulty experienced has been due to faulty burning of the lugs to the cross bars. Since the cells have now been in practically constant use for about seven months, the figures obtained are of some commercial value in estimating the probable cost of electric traction by accumulator cars. After carefully considering these, the Electric Traction Company feel satisfied that their original estimate of 4½d. per car mile is well within the mark. Messrs. Immisch's fleet of electric launches on the upper reaches of the Thames have met with great success, and in July and August the demand was so great that the resources of the Company were taxed to their utmost. Next season it is intended to increase the number of launches and stations.

The United Electrical Engineering Corporation has also been fully employed. A rigid rail Telpher line, having the exceptionally heavy grade of uniformly 1 in 11·5 has been erected from the Wood Green station of the Great Northern Railway up the hill to the Alexandra Palace. A line of a little over a mile and a quarter in length for the transport of 1,000 tons of tin ore per week is now in course of construction at the well-known Eastpool tin mine in Cornwall, and an order is also in hand for an equipment of a Telpher line in Rome. Contracts are, moreover, in the course of active negotiation for lines in South Africa. The prospects for the coming year are particularly favourable. Messrs. Crompton and Co. (Limited) have during the year carried out the whole of the contract work for the Kensington and Knightsbridge Company, including the erection and part equipment of two large central stations, each of which when complete will be on a scale sufficient to supply 130,000 10 candle-power lamps. These two stations are on the battery-transformer system. The underground mains already laid on Mr. Crompton's system are eight miles in length. At Chelmsford they have just on completion a central station for lighting the town on the alternating-transformer system. At Northampton they have secured the order for and are just commencing work on a central station on the battery-transformer system. At Swansea they have secured the order for and are just commencing work on a central station on the same system. At Port Barry they have nearly completed a central station on the combined high-tension series arc-lighting and alternating-transformer system. They have secured the contract and are now commencing work on a similar station at Folkestone, and have secured a contract for a central station for the Westminster Electric Supply Corporation. In addition to contracts for the complete supply of central stations, they have obtained large orders for plant of the same nature for the Central Argentine Railway; for a central station in Sweden; the Liverpool Electric Supply Company; and, finally, the Crompton Electric Supply Company of Australia. They have manufactured during the year a considerable quantity of depositing and metallurgical plant. Among these may be mentioned a very large dynamo, 2,500 amperes and 60 volts. They have supplied several sets of plant to the English and Dutch Admiralties. They have fitted up 11 steam ships complete, and supplied the steam dynamos for the White Star ships "Teutonic" and "Majestic." These two last are probably the lowest speed direct-driven sets ever constructed, the actual running speed being 170 revolutions for 110 volt lamps. In addition to this they have fitted up complete 93 installations, the

Digitized by Google

total number of lamps fitted in these installations being upwards of 11,500. Messrs. Paterson and Cooper report that the volume of their business has greatly increased: not only have more machines been sent out, but the average size is considerably larger than in previous years, while in their instrument department they have been exceedingly busy during the whole of the year. For ship lighting they have supplied a greater number of machines than in former years, both rope-driven and direct-running. Amongst the important installations carried out by this firm in 1889 were those of the Albert Institute, Dundee; the Pondardawe Tin Plate Works, South Wales; the Overton Paper Mills, Greenock; Messrs. J. and B Stevenson's Bakeries at Battersea; the factories of Messrs. Davis, Moore, and Co., Leicester; and the wharves of the Dundee, Perth, and London Shipping Company at Wapping. Messrs. Johnson and Phillips have been exceedingly busy in all departments. The principal increase has been in electric lighting work, and they are just completing Kapp alternate-current plants for three central stations—one for the Metropolitan Company in London, another for Keswick, and a third for Hong Kong. The growth of orders for the "Brockie-Pell" arc lamp has been remarkable. The largest order in London for these lamps is for the General Post Office, where 76 are to be placed in the sorting-room. The patent liquid insulator has also been in great demand during the year for overhead electric light wires. The works of Messrs. W. T. Goolden and Co. have during the year been fully employed in every department. During the year a considerable number of important contracts have been carried out, and others are now in hand, including central station plants, both on the Kapp-Goolden alternating system and with continuous-current plant. This firm has also been busy with electric mining plant. Messrs. Laurence, Paris, and Scott report that their manufacturing business shows promising signs of increasing, and during the year some excellent orders have been filled. This company exhibited at the Birmingham Exhibition, and many orders have resulted therefrom. The firm has now developed several patents, the principal ones being an instantaneous fuse, an improved system of laying underground mains, and an electric meter. This has been worked at for the last twelve months, and has passed through many stages to the present one, which is the outcome of long and tedious experiments, with many forms of working parts. Messrs. Drake and Gorham report extremely rapid progress during the year, necessitating a considerable extension of their offices. The supply and shipping of generating plant for central stations both at home and abroad has developed into an important department, but notwithstanding the increase in the number of central stations there has also been a brisk demand for complete installations, especially for country houses. In installation work Messrs. Drake and Gorham report the completion of the Bank of England, by the addition of two 9 horse-power gas engines to the existing 500-light steam plant; the Prudential Assurance installation, which now numbers 3,500 lights; Batsford Park, 300 lights; and the Inner Temple, where a 300-light steam plant has just been started. A department has been organised for foreign contracts, amongst which attention may be drawn to the Hotel Metropole, Sydney, 800 lights. The makers of electric light engines have also participated in the present activity. Thus Mr. Bumsted, of Hednesford, reports that his works are now more than double the size they were two years ago, and that he is fully employed turning out Chandler engines for electric lighting purposes. Makers of wires for electric lighting and telephone purposes have also been abnormally busy, and several firms report that they have been obliged to greatly increase their plant. In short, 1889 has been a period of exceptional development in almost every branch of electrical industry, and in view of the increasing popularity of the electric light, and of the slow but steady progress of electric traction, it is improbable that the next twelve months will witness any material diminution of activity.

(To be continued.)

ELECTRIC RAILWAYS AND TRAMWAYS IN THE UNITED KINGDOM.

Place.	Length.	System.	Worked by.
In Operation:—	Miles.		
Alexandra Park	½	Telpherage	United Electrical Engineering Company.

SUMMARY OF ELECTRICAL EVENTS FOR 1889.

JANUARY.

Paper on "Lightning Arresters and the Photographic Study of Self-Induction," read before the American Institute of Electrical Engineers by Mr. E. G. Acheson (8th).

First issue of the new fortnightly technical journal *The Telephone and Review of Electrical Science.*

First issue of the new monthly technical journal *Electric Power* (New York).

Opening of the Edison "up town" stations in New York.

Introduction of the Telephone into the Stock Exchange.

Exposure of the "Electric" Sugar Frauds.

Sir William Thomson's Inaugural Address before the Institution of Electrical Engineers, on "Ether, Electricity, and Ponderable Matter" (10th).

Appeal of Messrs. Gaulard and Gibbs against the judgment of Mr. Justice Kekewich, given on July 9, 1888, invalidating their transformer patents (12th).

The Leamington Town Council resolve to give twelve months' notice to the Midland Electric Light Company to determine the contract for lighting the streets (14th).

Formation of Elmore's Patent Copper Depositing Company, with a capital of £200,000 (18th).

Important decision of the United States Supreme Court, that an American patent was *not* limited in its duration by the shorter term of the foreign patent. This decision affected some of Mr. Edison's leading patents which had been taken out abroad for shortest period possible (21st).

Paper on "Electric Meters for Central Stations," read before the Society of Arts by Prof. George Forbes, F.R.S. (23rd).

Inauguration of the West Brompton Station of the House-to-House Electric Light Supply Company (24th).

Contract for the Electrical Equipment of the City and Southwark Subway Railway obtained by Messrs. Mather and Platt, of Manchester.

Circular issued by the Board of Trade, calling the attention of the Vestries to the fact that no Company has the right to disturb the streets without it possesses the necessary statutory powers (29th).

Publication of the Report of the Streets Committee of the City Commissioners of Sewers, with regard to the electric lighting of the City.

Publication of the Report of the Special Committee of the Kensington Vestry, appointed to consider matters relating to electric lighting.

FEBRUARY.

Society of Arts Motor Competition Award.

Judgment given by the Appeal Court in favour of the Edison Incandescent Lamp Patent, in the action of Edison-Swan Company *v.* Holland and others. No injunction, however, was issued against the Anglo-American Brush Corporation, who were third parties to the suit (18th).

The City Commissioners of Sewers decide to invite tenders for the electric lighting of the City (26th).

Completion of the new Triplicate Cable between Java and Australia.

The Town Council of Bath decide to have underground in lieu of overhead wires.

Edison Convention held in Kansas City.

National Electric Light Association Meeting at Chicago.

Paper on "Alternate-Current Machinery" read by Mr. Gisbert Kapp before the Institution of Civil Engineers (19th).

Paper on "Some European Central Stations and their Lessons," read by Prof. George Forbes before the Institution of Electrical Engineers (28th).

MARCH.

Judgment of the Court of Appeal in the case of Ferranti *v.* Gaulard-Gibbs, upholding the judgment pronounced by Mr. Justice Kekewich on July 9, 1888, by which the Gaulard-Gibbs' transformer patent was revoked (4th).

Cancellation of the Edison Patents in Canada.

Paper on "Arc Lamps and their Mechanism," read before the Society of Arts by Prof. Silvanus Thompson (6th).

Lecture at the Royal Institution by Dr. Oliver Lodge, "On the Discharge of a Leyden Jar" (8th).

Collapse of the French Copper Syndicate.

The Cheltenham Town Council decide to invite tenders for the erection of a central lighting station (11th).

Visit of the Technical Press to the Series Electric Tramway at Northfleet (13th).

Paper read before the Royal Society by Mr. Shelford Bidwell, "On an Effect of Light upon the Magnetisation of Iron" (21st).

Phonopore Demonstration on a Telegraph Wire between St. Pancras and Leicester (26th).

Inspection of Mr. Webster's Electrolytic Treatment of Sewage by the Technical Press (27th).

Death of Mr. C. H. B. Patey, C.B., Secretary for Postal Telegraphs

Important storage battery patent decision rendered in the United States' Circuit Court by Judge Cox. The two patents of J. W. Swan for the preparation of plates with perforations were declared invalid, and the Faure patent for applying the active material mechanically was narrowed to that in which the active material takes the form of a "paint, paste, or cement." These patents are the property of the Electrical Accumulator Company.

Digitized by Google

APRIL.

Transfer of the Continental Cables to the Government, the price paid for the cables of the Submarine Telegraph Company being £22,330 (1st).
Opening of the Board of Trade Inquiry into the Metropolitan electric lighting schemes (3rd).
Publication of Prof. Forbes' Report to the Electric Lighting Committee of the Paddington Vestry.
The Chelmsford Town Council accept the tender of Crompton and Co. (Limited) to light the public thoroughfares of the borough for five years with 18 1,000 candle-power arcs and 200 32 candle-power incandescents, at a total cost of £873 per annum.
Death of Mr. Warren de la Rue (19th).
Death of Mr. R. S. Newall.
A large number of overhead wires cut down by order of the New York Board of Electrical Control.
Paper read before the Institution of Electrical Engineers by Dr. Oliver Lodge, on "Lightning, Lightning Conductors, and Lightning Protectors (25th).
Completion of the alternative cable to the Cape of Good Hope (30th).

MAY.

Close of the Board of Trade Inquiry into the Metropolitan electric lighting schemes, after having sat for 18 days (1st).
Opening of the Paris Exhibition (6th).
Opening of a central station at Glasgow.
Royal Society Conversazione (8th).
Issue of an electric lighting licence to the Dublin Corporation (9th).
The Boston Board of Aldermen grant permission to the West End Railway Company to use electric traction on all their existing lines.
The London Central Subway Bill for the construction of an electric railway subway between Holborn-circus and Piccadilly came before a Select Committee of the House of Commons (9th).
Experiments at Portsmouth with regard to the use of the electric light in night attacks.
Publication of Major Marindin's Report on the Metropolitan electric lighting schemes (20th).
Annual Meeting of the American Institute of Electrical Engineers in New York (22nd).
Paper on "Alternate-Current Working," read by Mr. W. M. Mordey before the Institution of Electrical Engineers (23rd).
Rejection of the London Central Subway Bill by the Select Committee of the House of Commons (23rd).
Completion of the Telephone Amalgamation Scheme, whereby the National Company bought up the United and Lancashire and Cheshire Companies; the new arrangement taking effect as from May 1st.
Conversazione of the Institution of Electrical Engineers (24th).
Death of M. Gaston Planté (24th).
Consolidation of the Edison Electric Light interests in America.
Completion of the Thomson-Houston Electric Railway at Topeka (Kansas).
The capital of the American Bell Telephone Company increased from $10,000,000 to $20,000,000.

JUNE.

Formation of the Electric Construction Corporation, with a capital of £500,000 in £10 shares. This Company acquired the works and business of Elwell-Parker (Limited), the Electrical Power Storage Company (Limited), and the Railway Electrical Contractors (Limited), together with the Julien and Sprague electric traction patents for Great Britain (4th).
Provisional Order granted to the Corporation of Swansea.
Important letter addressed to the Board of Trade by the London County Council on the subject of the Metropolitan Electric Lighting Schemes (4th).
Board of Trade Inquiry at Dublin to hear an application by the Alliance and Consumers' Gas Company for permission to open certain streets for the purpose of laying electric light cables (6th and 7th).
Royal Society Conversazione.
Issue of the Board of Trade "Model Order."
Deputation to the Board of Trade on the subject of the establishment of an Electrical Standardising Laboratory (19th).
The Brush Patent, No. 2003 of 1878, for compound winding, and a peculiar form of commutator, invalidated by the judgment of Lord Trayner in the Court of Session, Edinburgh (26th). This result arose out of the action of King, Brown, and Co. *v.* Anglo-American Brush Corporation.
During the last few days of June numerous notices of intention to apply for Provisional Orders were served upon the Local Authorities in the provinces by various electric lighting companies.
A large number of electric supply companies registered, amongst them 11 provincial House-to-House Companies, each with a capital of £100,000 in £5 shares.
The Glasgow Corporation decide to apply for electric lighting powers (24th).

JULY.

The Bill for the purchase of the telephone lines by the State passed by the French Chamber of Deputies.
The Board of Trade advised by Major Marindin not to accede to the request of the Dublin Gas Company to be allowed to break up the streets for the purposes of electric lighting.
Issue of the report of the first six months' working of the Electrical Trades Section of the London Chamber of Commerce.
An agreement entered into by the Edison-Swan United Electric Lighting Company and the Anglo-American Brush Electric Light Corporation, whereby the Edison-Swan Company accepted a licence to use the Lane-Fox and other incandescent lamp patents held by the Corporation and agreed to pay the Corporation a royalty; the Corporation, on the other hand, agreeing to give up the manufacture of incandescent lamps in the United Kingdom and to pay the taxed costs of the patent litigation which had taken place between the two companies.
The Metropolitan Electric Lighting Schemes come before a Select Committee of the House of Commons (16th).
Formation of an English Westinghouse Company, with a capital of £600,000 in £10 shares.
Amalgamation of the Anglo-American Brush Electric Light Corporation with the Falcon Engine and Car Works, and with the Australasian Electric Light, Power, and Storage Company; the amalgamated Companies to be known in future as the Brush Electrical Engineering Company (Limited).
The Corporation of Hamilton decide to apply for electric lighting powers.
The Select Committee of the House of Commons on the Metropolitan Electric Lighting Schemes, after having amended the Bills in several particulars, reported to the House (19th).
Circulars issued by the Electrical Section of the London Chamber of Commerce respecting Standard Types of Apparatus and the Proposed Government Standardising Laboratory.
Consolidation of the various Westinghouse electrical interests; the Westinghouse Electric Company to be reorganised under the name of the Westinghouse Electric and Manufacturing Company (Limited).

AUGUST.

Opening of the Electrical and Industrial Exhibition at Bingley Hall, Birmingham (1st).
The streets of Montreal wholly lighted by electricity, 753 arcs and 346 incandescents being employed (1st).
The Metropolitan Electric Lighting Schemes come before a Select Committee of the House of Lords (6th).
Meeting of the National Electric Light Association at Niagara Falls (6th).
Convention of the Edison Illuminating Companies at Niagara Falls.
The Electric Lighting Provisional Orders Bill read a third time in the House of Lords and passed (15th).
Registration of the Brush Electrical Engineering Company (Limited), with a capital of £750,000.
Formation of the Fowler-Waring Cables Company (Limited), with a capital of £200,000. This Company acquired and united the electric cable businesses carried on by John Fowler and Co. (Leeds) and by Mr. R. Waring.
Issue of the Board of Trade Rules with regard to overhead wires (22nd).
Opening of the International Congress of Electricians at Paris (24th).
Royal Assent given to the Metropolitan Electric Supply Bill (26th).
The Fleetwood Improvement Commissioners decide to apply for a Provisional Order.
Royal Assent given to the Electric Lighting Provisional Orders (Nos. 2, 3, 4, and 5) Bills (30th).
The Dublin Corporation decide by 38 to 3 votes to apply for sanction to borrow £50,000 to carry out the provisions of their electric lighting licence.
The Corporations of the following towns decided during the month to apply for Electric Lighting Powers:—Huddersfield, Leicester, Manchester.

SEPTEMBER.

The French Government take possession of the telephone system of France (1st).
Completion of the Vienna-Prague Trunk Telephone Line, a distance of nearly 200 miles (6th).
The fifty-ninth meeting of the British Association, Newcastle-on-Tyne (11th).
Death of Mr. Cyrus Legge, one of the promoters of the Atlantic Cable (19th).
Opening of the Bradford Municipal Central Lighting Station (20th).
Meeting of the American Association for the Advancement of Science at Toronto.
Meeting of the National Telephone Association at Minneapolis.
Paper on "A New Alternating-Current Motor," read before the American Institute of Electrical Engineers by Lieut. J. F. Patten (10th).

Digitized by Google

The Corporations of the following towns decided during the month to apply for electric lighting powers :—Chester, Hove, Lancaster, Walsall.

OCTOBER.

Publication of the Paris Exhibition Awards.
The Canning Town Section of the North Metropolitan Tramway Company's system worked entirely by the accumulator cars of the Electric Traction Company (1st).
Meeting of electrical engineers and linemen to discuss the formation of an Electrical Trades Union (5th).
Death of Dr. Joule (10th).
Death of Sir Daniel Gooch (15th).
Death of M. Louis Curchod, Director of the International Telegraph Bureau (18th).
The Edison Incandescent Lamps Patent upheld in the United States Circuit Court at Pittsburgh.
The Taunton Electric Lighting Company decides to increase its capital to £20,000 (21st).
Violent agitation in New York on the subject of overhead wires, consequent upon the death of a lineman due to his coming in contact with an electric light circuit.
Consolidation of the Brush Company of Cleveland and the Thomson-Houston Company of Boston.
The Corporations of the following towns decided, during the month, to apply for electric lighting powers :—Aberdeen, Airdrie and Coatbridge, Bacup, Bedford, Birkenhead, Burslem, Cambridge, Croydon, Dundee, Kingston-on-Thames, Oldham, Nottingham, Stafford, Worcester.

NOVEMBER.

First Annual Dinner of the Institution of Electrical Engineers (4th).
Special Meeting of the Electrical Trades Section of the London Chamber of Commerce, at which several important resolutions were passed relating to the forthcoming Exhibition at Edinburgh (11th).
Formation of the Massachusetts Electric Lighting Association.
The Blackpool Electric Tramway Company declares a 7 per cent. dividend (23rd).
Successful demonstrations of the Phonopore in Spain.
The Corporations of the following towns decided during the month to apply for electric lighting powers :—Burton-on-Trent, Burnley, Derby, West Bromwich, Wigan, Paisley, Wolverhampton, York, Great Yarmouth, Dover, Newcastle-under-Lyme, Barnsley, Wednesbury, Tiverton, Portsmouth, Ayr, Hull, Hastings.

DECEMBER.

Opening of the Municipal Central Station at the Halles Centrales, Paris (1st).
The London County Council vote £2,000 for the equipment of a municipal testing laboratory (3rd).
The City Commissioners of Sewers award the contract for the lighting of the Central District of the City to the Brush Electrical Engineering Company (3rd).
Edison's Canadian incandescent lamp patent upheld on the rehearing of the action brought by the Royal Electric Company of Canada against the Edison Company.
Amalgamation of the Edison General Electric Company and the Sprague Electric Motor Company.
Termination of the Silvertown Strike.
Contract for the arc lighting of the Edinburgh Exhibition awarded to the Brush Company—three hundred and fifty 2,000 candle-power lamps.
During this month a large number of sensational reports of fatal accidents due to electricity reached this country from the United States.

NEW COMPANIES REGISTERED IN 1889.

The following is a list of the more important new Companies dealing with electricity which have been registered during the past year :—

Name of Company.	Capital.
Alcoy and Gandia Railway and Harbour Company	£525,000
Bath Electric Light Company	25,000
Birmingham House-to-House Electricity Company	100,000
Birmingham Safe Deposit Company	20,000
British Tanning Company	70,000
Brompton Electric Fittings Company	2,000
Brush Electrical Engineering Company	750,000
Cambridge University and Town Electric Lighting Company	50,000
Chelsea Electricity Supply Company	100,500
Chili Telephone Company	250,000
Column Printing Telegraph Syndicate	10,000
Crompton Electric Supply Company of Australia	50,000
Crompton-Howell Electrical Storage Company	19,600
Croydon Electric Supply Company	5,000
Devon and Cornwall Electricity Supply Company	100,000
Dutton and Co.	60,000
Economic Gold Extraction Company	175,000
Ecuador Telephone Company	100,000
Electric Arms and Ammunition Company	40,000
Electric Construction Corporation	500,000
Electric Tramcar Syndicate	20,000
Electric Trust	60,000
Electric Wiring and Fittings Company	5,000
Electrical Accessories Company	5,000
Electrical Power Storage Company	200,000
Electricity Supply Company for Spain	100,000
Electricity Supply Corporation	100,000
Elmore's Foreign and Colonial Patent Copper Depositing Syndicate	120,000
Elmore's Patent Copper Depositing Company	200,000
Foreign and Colonial Electrical Power Storage Company	100,500
Fowler-Waring Cables Company	200,000
Galloways	250,000
General Electric Company	60,000
Halifax and Bermudas Cable Company	120,000
Halifax Mutual Electric Light and Power Company	20,000
Henley Telegraph and Electric Construction Company	200,000
Hulett, D., and Co	35,000
Irish House-to-House Electricity Company	100,000
Jensen Electric Manufacturing Company	80,000
Johannesburg Electricity Supply Company	250,000
Kensington and Knightsbridge Electric Light Supply Company	250,000
Keswick Electric Light Company	5,000
Kingston-upon-Hull Electric Lighting and Supply Company	1,000
Laing, Wharton, and Down Construction Syndicate	40,000
Lancashire and Cheshire House-to-House Electricity Company	100,000
Lange and Company	10,000
Leicester Electric Light and Power Company	1,000
Liverpool House-to-House Electricity Company	100,000
Llanelly Electric Light and Power Company	15,000
London Electric Supply Corporation	1,250,000
Manchester House-to-House Electricity Company	100,000
Maquay Syndicate	12,000
Maxim-Weston Electric Company	75,000
Midland House-to-House Electricity Company	100,000
Miners' Lamp Electric Lighting Company	3,000
Mines and General Telpher Company	4,000
Morris Brothers	5,000
Mudge-Marchant Engine Company	131,105
Municipal Electric Light and Power Corporation	25,000
National Electric Supply Company	100,000
Newcastle and District Electric Lighting Company	50,000
Newcastle-upon-Tyne Electric Supply Company	50,000
Northampton Electric Light and Power Company	20,000
Northern Electric Wire and Cable Manufacturing Company	20,000
Northern House-to-House Electricity Company	100,000
Nottingham Electric Light and Power Company	100,000
Notting Hill Electric Lighting Company	100,000
Peru Telephone Company	100,000
Pilsen-Joel and General Electric Light Company (now Gwynne-Pilsen Electric Company)	200,000
Planet Electrical Engineering Company	20,000
Pontypridd Electric Lighting Company	10,000
Portsmouth and South Hants Electricity Supply Company	50,000
Railway Automatic Electric Light Syndicate	10,000
River Plate Electricity Company	500,000
Ruston, Proctor, and Co.	250,000
Scottish Automatic Supply Company	12,500
Scottish House-to-House Electricity Company	100,000
Series and General Electric Traction Company	200,000
South of England House-to-House Electricity Company	100,000
Sunderland and District Electricity Supply Company	100,000
Taylor and Challon	40,000
Western House-to-House Electricity Company	100,000
Westinghouse Electric Company	600,000
Westminster Electric Supply Corporation	100,000
Williamson Electrical and Engineering Company	5,000
Woking Electric Light Supply Company	20,000
Wolverhampton Electric Light and Power Company	50,000
Woodhouse and Rawson United	350,000
Wrexham and District Electric Light Supply Company	20,000
Yorkshire House-to-House Electricity Company	100,000

COMPANIES WOUND UP IN 1889.

Amongst the companies against which winding-up orders have been granted during the past year are the following :—

Electric Apparatus Company.
Electrical Automatic Delivery Box Company.
Luther Hanson and Co.
New Telephone Company.
Schmidt-Douglas Electric Company.
Self-Winding and Synchronising Clock Company.

Digitized by Google

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 21, 1889.

The Overhead Wire Cutting in New York.—The electric light situation in New York has developed another phase during the past week. It will be remembered that about two months ago, at the time it was proposed to begin the wholesale cutting down of the overhead wires, one of the judges interposed with an injunction, under cover of which the local companies removed a large quantity of their underwriters' wire and replaced it with circuits of insulated wire of the latest and most approved insulation. The action of this judge was appealed against by the authorities, and now the General Term of the Supreme Court in this State has reversed the order, and has given the Commissioner of Public Works authority to remove the wires condemned by the Board of Electrical Control. The opinions of three judges are practically summed up in the following:—"Plaintiffs have been guilty of a wilful violation of a manifest duty in allowing these wires to become dangerous. They are without excuse, and when they claim that the destruction of these instruments of death maintained by them in violation of every debt of obligation which they owe to the public is an invasion of their rights of property, such claim seems to proceed on the assumption that nothing has a right to exist except themselves." It will be obvious that this language refers to such circuits as the companies had in use prior to the granting of the injunction, and could hardly be applied with propriety to the new circuits strung lately. But, of course, armed with such an authority, the Board of Electrical Control and the Commissioner of Public Works have rushed to wreak their vengeance on the obdurate companies, and have begun a merciless campaign against all the wires in the district provided with subways. The result is that during the past week the busiest thoroughfares of the city have been alive with gangs of men actively engaged in cutting down and removing poles and wires, and a further result has been that the streets have once more been reduced to darkness. It would have been a kindly act toward the store-keepers to have the circuits remain up during these few days preceding Christmas. As might be expected, the darkness of the streets has been very much of an impediment to shopping at night, and the consequence is that the stores have been crowded to suffocation, and dangerously, during the day time. It has so happened, too, that we have had a spell of infamous weather, heavy snow being followed by rain and fog, so that the heartiest kind of invitation has been extended to the sandbagger and other midnight prowlers to enlarge their spheres of operations in this city. In some of the streets the gas lamps have been restored, but it is really pitiful to see how dark they leave the sidewalks after the brilliant illumination of the arcs. Meanwhile, the local companies are endeavouring to get their underground wires and cables ready as quickly as possible; but it stands to reason that some weeks must elapse before the service can be restored to any state of efficiency. The local companies have, in addition to the expenses attending this work, to stand the loss occasioned by the destruction of their pole lines and aerial wires, whose cost ran into a great many thousand dollars.

The Overhead Wire Question in Boston.—I may supplement what I said with regard to Boston last week with the remark that not the slightest evidence has yet been adduced to substantiate the first report sent out to the effect that the recent disaster started with a fire of electric origin in the head-quarters of the Boston Time Company. As I wrote you, however, there has been a great deal of investigation on the subject, and Mayor Hart has been on a tour of investigation through the country to ascertain what are the methods of regulation for overhead wires in force in other cities. A report has now been submitted to the Board of Aldermen from the Electric Light Committee, in which it is recommended that all dead wires shall be taken down at once; that wires entering buildings shall be protected by proper insulation, or suitable safety fuse protectors; that the wire of the West End Electric Railway shall be protected by guard wires; and that an official shall be appointed by the city, who shall have authority to control and regulate overhead wires, and to remove any wires at any time which he considers to be a menace to public safety. It will be found that the task of removing dead wires is not a light one, for they ramify in every direction in Boston, and have been allowed to stay up even more freely than in New York, where the Board of Electrical Control has, from the first, made war upon them. It may be noted that of telephone wire alone there is a total length of 5,168 miles in Boston, of which more than one-third is still overhead, 400 miles being exposed wires. The New England Telegraph and Telephone Company has, however, been quite active and prompt in getting its wires underground, and is still carrying on the work with as much vigour as possible. It is not unworthy of note that the wires of the Telephone Company have for a few years past been protected by safety fusible strips. The telegraph people have also done considerable underground work in Boston. The prospect now is that they will do much more.

The Electric Railroad Under Snow.—I alluded in the opening paragraph to the fact that we have been visited by a heavy snow storm. It is quite early in the year for snow to visit this part of the country, and hence the trial of the severity of the winter on the new electric roads has come much sooner than it was looked for. The results have been highly satisfactory, especially in Boston, where three long lines are already equipped electrically with apparatus of the Thomson-Houston Company. On all these lines the West End Company employed its electrical snow-ploughs, the result being that the tracks were cleared of snow very effectively, and yet not in the ordinary manner of scattering the snow and the mud all over the street and the passers-by. The cars showed themselves well able to travel on the heaviest grades, despite the greasiness of the rails, and carried their full load under conditions that would have exhausted double teams of horses hauling half the load.

Mr. Dana Greene on the Development of Electric Traction. The New York Electrical Society listened last week to an extremely interesting extemporaneous address from S. Dana Greene, late of the Sprague Company, on the subject of the development of electric traction. Mr. Greene has seen a great deal of service, and was associated with Mr. Sprague in the memorable pioneer work on the Richmond road—which, by the way, has been rescued from the financial sharks who secured control of it, and is being put into condition to do better work than before. In addition to discussing the work that had already been done, Mr. Greene threw out some suggestions as to the lines on which the work might be followed out in the future. Thus he suggested that there would probably be a return to the use of one motor for the car, instead of employing as at present two motors, one on each axle. Of course, this would require a remodelling of the present form of truck, and the mounting upon wheels not less than 36in. in diameter; but he fully believed that the time was coming when we would see a single motor of 40 or 50 horse-power on a single car, and equal to all the strains that could possibly be put upon it. He also advocated increase in the length of the wheel base, and expected to see the substitution of bogie trucks: instancing Boston, where a car is running with a body mounted on a truck having three pairs of wheels. With regard to the overhead system in general, Mr. Greene said that all statistics and results went to show that it effected a saving of 50 per cent as compared with the cost of operation with horses. Respecting the conduit system, Mr. Greene expresses himself in a very hopeful manner; and there can be no doubt that marked improvements are to be expected in this department, several leading inventors, including Mr. Edison, being busily engaged with experiments on this class of work. It is recognised that in a great many of the large cities the feeling against overhead wires is too strong to be overcome. It is also felt by many that the storage battery system is still too uncertain and too expensive, but it is believed that a practical solution of the question can be found in some form of conduit service. The test of the Bentley-Knight system in Boston is not regarded by any one as having been a thorough one or a fair one; for even if the conduit itself had worked well, the fact that it served as gutter for the whole street was enough to condemn

Digitized by Google

it to failure. Mr. Greene also alluded to the storage battery system in a manner far from despairing, but did not consider it applicable to roads with grades of over 5 per cent. It may be noted in this connection that Mr. William Wharton, jun., who enjoyed at one time the advice and assistance of Mr. Anthony Reckenzaun, has been pegging away industriously at the problem in Philadelphia, and that he has now equipped the Lehigh Avenue Street Railway Company's road for operation with storage batteries, there being six cars now ready for service. The largest, which is 30ft. over all, the body being 22ft. long, made its first run very successfully all through the city on December 12th. It has a 15 horse-power motor on each of its two tracks. The smaller cars are 16ft. long, and have two 10 horse-power motors suspended side by side on the truck. A noticeable feature of the car is that the storage batteries are inserted and removed from the cars through the end panels instead of through the side of the car, as has hitherto been the practice. In connection with this road, a handsome car station has been put up, and the equipment is in every way first class. The work is in good hands and the results are looked for with very great interest.

The New Edison Station at Brooklyn.—The work in the fine new Edison station at Brooklyn, New York, receives elaborate treatment in the *Electrical World* this week, which publishes a long and able article on the subject by Mr. C. J. Field, its engineer, accompanied by a large number of illustrations and detail drawings. The station is principally noteworthy for two features. One is the use of high-speed compound engines, Edison stations heretofore having confined themselves to single-cylinder high-speed engines. The Ball engines employed were intended to run at first at 250 horse-power, but it was lately determined to operate them at a maximum capacity of 300 horse-power, and they have repeatedly been loaded without difficulty up to 330 horse-power, reaching these results on an average consumption of about 23lb. of water per horse-power, and 3lb. of coal to the horse-power per hour for the 24 hours. The other special point is the abandonment of feeder equalisers. As Mr. Field points out, these equalisers were not employed in Edison's earlier stations, but were adopted later as a supposed element of economy. Experience has now, however, satisfactorily demonstrated that their merit as an element of economy and close regulation is not as great as was estimated, and hence for some time past the smaller Edison stations have gone back to the original plan. The absence of the feeder equalisers has been met by a more liberal use of copper and by the thorough interlacing of the distribution system, so that pressure is maintained practically constant throughout. The Brooklyn station is the first of the large new Edison stations to get back on the old basis, and has constituted a confirmation of Mr. Edison's well-known opinion that the extra outlay of copper more than counterbalances the longer life of the lamps, as the result of uniform pressure and the decreased loss of energy in the conductors, owing to their lower resistance. In the underground system employed also there are a few improvements, and the iron tubes used have been made larger, so that an increased thickness of insulation is obtained. This station is already commanding a large amount of business, and bids fair to be highly profitable.

CORRESPONDENCE.

ELECTRIFYING STEAM.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to Dr. Lodge's letter in *The Electrician*, p. 174, I need hardly say that I was well acquainted with his important work relating to the electrical deposition of dust and the dissipation of fog: indeed, I was present at his lecture at the Royal Institution when it was so ably described and so effectively illustrated.

But after carefully considering Dr. Lodge's experiments, together with the explanation which he gives of them, in connection with my own observations of the effect of electrification upon a steam-jet, I formed the opinion that the phenomena in the two cases were by no means "essentially identical." I may mention three reasons for this conclusion—(1) The smoke-deposition is distinctly a polar effect, while the steam-jet phenomenon presents no indication of polar action. (2) In Dr. Lodge's experiments, electrification for some two or three seconds is necessary to produce sensible condensation: in mine the electrical action is, as far as one can see, instantaneous. I showed at the Physical Society that the full effect could be produced at least eight or ten times in a second. (3) The electrical discharge which acts so conspicuously in the case of the steam-jet, is quite without influence upon the apparent density of a smoke-jet, formed by forcing smoke-laden air through a glass nozzle by means of a foot-blower.—Yours, &c.,

December 30, 1889. SHELFORD BIDWELL.

UNDERGROUND MAINS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have read with great interest the article written by Mr. Sayers on the underground mains of the Hastings Electric Light Company. I may mention that I have laid several miles of indiarubber-covered cables underground, and have found them perfectly satisfactory. I have no doubt from the description given that I have used very much the same cable as that used by Mr. Sayers. The chief thing I have found is to be very careful concerning the reaming of the pipes and the drawing in of the cable. It seems hardly possible, but nevertheless I have found it to be a fact, that there are electrical engineers (so called), holding responsible positions in London, who think that there is nothing whatever in underground work, and that any foreman who can open up the road is capable of laying underground mains for electric light. Is it any wonder we hear of failures in underground mains?—Yours, &c.,

A PRACTICAL ELECTRICAL ENGINEER.

London, Dec. 31, 1889.

"ELECTRIC LIGHT IN ENGLISH TOWNS."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the letter over my initials in last week's issue there was an important omission, inasmuch as the remarks referred to the section concerning Liverpool.

That was the first to meet the eye, and as at this time of year there is rather a pressure of business, there was little leisure to scan the whole report; so I can only hope the remainder was less inaccurate than the section I commented on in the last number.—Yours, &c., C. H. Y.

A CORRECTION.—In Mr. James Johnstone's letter on "Flames and Electricity," which appeared on p. 200 of our last issue, the commencement of the last sentence but one should read, "The one end of the tube should be pointed for the gas to burn at, the other end should be," &c., &c.

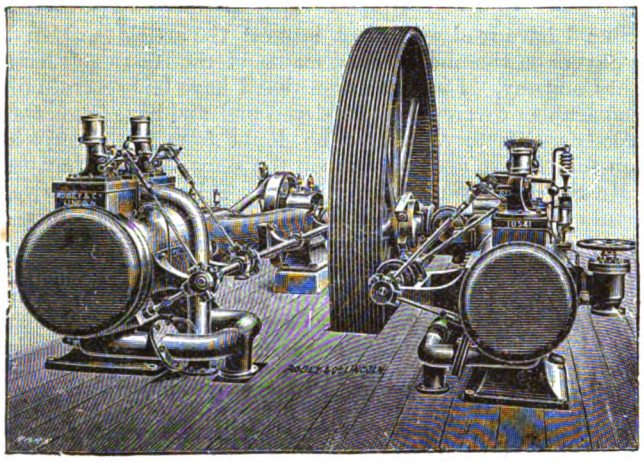
ROBEY ELECTRIC LIGHTING ENGINES.

The illustration below shows one of Messrs. Robey and Co.'s improved coupled compound horizontal fixed engines, fitted with patent automatic trip expansion gear. The engine is specially designed for large, permanent electric light installations, mills, factories, &c. A special feature is the automatic valve gear. The steam is admitted by two Cornish equilibrium valves, one at each end of the cylinder. These are lifted alternately by a fixed eccentric, so as to give a constant lead, while the point of release, and therefore of cut-off, is decided by the governor. The latter is very delicate in its action, and, being relieved of all working strain, is so constructed as to give a wide range of cut-off, with very slight variation in speed. The admission is full, and the cut-off is sharp and distinct at all points. As the valves move almost in equilibrium the friction and consequent wear and tear are reduced to a minimum. The exhaust consists of a special arrangement of Corliss valve, which gives a quick wide opening to the exhaust, with a very small travel, and the exhaust valves being placed under the cylinder, this is kept constantly drained. For electric light installations the valve gear can be controlled by the "Richardson-Nevile" electric regulator, which enables the engine to be controlled by the electric current itself. The valve gear is so arranged that the engine can be stopped by merely pulling a cord, and the engine is designed to work at from 80lb. to 100lb. pressure. High pressure single engines

Digitized by Google

are made of this type from 10 horse-power nominal to 50 horse-power nominal, and coupled and compound engines from 20 to 100 horse-power. The engine will give out the best duty when developing about 2½ times its nominal power, but is made of sufficient strength to work up to four times the nominal power.

Amongst other engines recently designed by Messrs. Robey and Co. for electric lighting purposes may be mentioned (1) a vertical high-speed engine, mounted on a cast-iron bed-plate, the other end of which carries the dynamo. The bed-plate is provided with lugs and adjusting screws, to admit of the driving belt being tightened without stopping the machinery; (2) a horizontal high-speed engine, with bed for dynamo; (3) a high-speed compound horizontal engine, specially designed for driving dynamos either direct or from the fly-wheel. In this engine the moving parts are all made of steel, the piston and rod in one piece, the crank running in very long gun-



Robey Coupled Compound Horizontal Engine.

metal bearings. The working parts are enclosed within the base plate, or hinged cones surrounding the cranks, the lubrication being specially provided for.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"The Electrician" Electrical Trades' Directory and Handbook, 1890.—We call the attention of the electrical public to the fact that entries for insertion in the Alphabetical and Classified Trades Sections of the forthcoming edition cannot be inserted in their proper places if received after Tuesday next, January 7th.

Cable for Sale.—The Corporation of Trinity House offer for sale about nine miles of submarine telegraph cable recently used for communicating between Walton-on-the-Naze and the Sunk Light Vessel, together with instruments, &c., connected with the working thereof. Tenders are to be addressed to Mr. J. Inglis, Secretary, on or before Monday, the 27th inst. Further particulars are given on page xiii. of our advertisements.

Mavor and Coulson.—The firm of Muir, Mavor, and Coulson, electric engineers, of Glasgow, of which the subscribers were the sole partners, was dissolved by mutual consent on November 30, 1889. The subscribers, Henry Alexander Mavor and William Arthur Coulson, have acquired right to the business, stock-in-trade, and goodwill of the dissolved firm, and will discharge its liabilities. Mr. Sam. Mavor, who has been with the dissolved firm since 1885, has been taken in as partner, and business will in future be carried on in conjunction with him, at 56, George-square, Glasgow, under the title of Mavor and Coulson.

Telegraph Manufacturing Company, Helsby.—We have received a copy of Catalogue, Section A (Wires and Cables), published by this Company. The Catalogue embodies several new features, and is copyright. It contains a weight and resistance table, a wire price list ready reckoner, sizes of given weights of copper wire, instructions how to determine the size of conductors for electric light and power, some useful formulæ relating to mains, and a number of tables dealing with gutta-percha, india-rubber, vulcanised rubber, compound rubber, lead, silk, and cotton-covered wires, flexible cords, and also gives particulars of the lightning conductors, telegraph, telephone, electric light, military, railway, and elevator cables, manufactured by the firm, besides descriptions of casings, cleats, saddles, wood screws, jointing materials, &c., &c.

Electric Apparatus Company (Limited).—It will be seen by reference to our advertisement columns that the stock-in-trade and goodwill of this Company (in liquidation), of 4, Charing-cross, London, S.W., have been purchased by Woodhouse and Rawson United (Limited), of 88, Queen Victoria-street, London, E.C.

Electric Light Fire Risks.—The North British and Mercantile Insurance Company may now be included amongst the offices who are issuing revised Electric Light Fire Risk Rules, to meet the growing demand for the electric light. We have recently received an advanced proof of these rules, which are necessarily constructed upon the lines of those issued by other offices, such as the Phœnix, Guardian, &c. The rules of the North British are, of course, compiled with the advantage of the experience gained during the past year, and insist upon use of only the best materials, perfect insulation, constant care and attention to details, and the providing of measuring instruments, switches, cut-outs, &c., of the most approved makes. A copious Index is included in the Rules.

——— The 16th Edition of the Phœnix Fire Office Rules regulating the installation of the Electric Light will shortly be issued.

The Société Électricité et Hydraulique.—We have received from the Société Électricité et Hydraulique of Charleroi several illustrated pamphlets describing the different apparatus manufactured by them, including dynamos, arc lamps, gas engines, hydraulic motors, &c. The Dulait dynamo, which is built by this company,

PATENT
SILICIUM BRONZE AND SILICIUM COPPER WIRE.
The best for overhead Telephone and Telegraph Lines,
AND ALL ELECTRICAL PURPOSES.
Hard Drawn High Conductivity Copper Wire.
ROLLED AND DRAWN
PHOSPHOR BRONZE.
PHOSPHOR BRONZE
BEARINGS, BUSHES,
AND OTHER PARTS OF
ELECTRICAL MACHINERY.
SOLE PROPRIETORS of the British, Indian and Colonial Patents,
THE PHOSPHOR BRONZE COMPANY (Limited),
87, Sumner Street, Southwark, London, S.E.
WIRE AND SHEET MILLS: BAGOT STREET, BIRMINGHAM.

Digitized by Google

is a 4-pole machine, closely resembling the well-known Gülcher dynamo. The chief feature of the Dulait arc lamp is the use of a vibrator device to bring the carbons together. The Société Hydraulique also make a lamp in which the arc is reversed, all the light being obtained by reflection, a system of illumination which they assert is very economical when properly arranged. Another special piece of apparatus is the Pylone Hydro-Électrique, which is a handsome wrought-iron mast supporting a group of arc lamps, in the base of which a small dynamo, driven by a hydraulic motor, is installed. Several of these masts are in use at Liége, the motors being supplied with water at about 80lb. pressure from the town mains.

EDISON ELECTRIC LIGHT Co. (New York).—This Company's sheet, recently received, contains a most formidable list of the isolated plants erected by the Company; companies working the Edison patents under licence from this Company, patents owned by the Company, together with illustrations of Edison dynamos and lamps. The isolated plants, central stations, and municipal plants, represent the respectable total of 1,727 installations and 1,124,686 lamps. A revised set of figures will be issued shortly, when a large increase on these figures may be anticipated.

PATENT RECORD.

APPLICATIONS FOR PATENTS.

December 16, 1889.

20,186. H. W. WILSON. Norwich. Measuring or metering electric currents, as used in houses, &c., for measuring the amount of current used.

20,218. D. B. MORISON. London. Improvements in telephone transmitters.

20,235. E. CORRENS. London. An improved method of and means for the production of the grids of electric accumulators in which the bars narrow from each side inwards.

20,236. W. W. HORN. London. An improved combined electric igniting device and extinguishing device for lamps (M. Carranza, J. M. Sinoco, and Y. Altozano, United States).

December 17, 1889.

20,244. J. H. HOLMES. Newcastle-on-Tyne. Improvements in electric generating machinery for use in connection with the electric lighting of railway trains.

20,260. F. STITZEL, C. WEINEDEL, A. REUTLINGER, M. J. SCHWARTZ, J. H. EGELHOFF, and J. KRIEGER, Senior. Glasgow. Improvements in electric semaphores.

20,261. F. STITZEL, C. WEINEDEL, A. REUTLINGER, M. J. SCHWARTZ, J. H. EGELHOFF, and J. KRIEGER, Senior. Glasgow. Improvements in electric semaphores.

20,266. H. H. LAKE. London. Improvements in and relating to electric spark-rupturing appliances (E. Thomson, United States).

20,268. H. B. TATHAM and J. TATHAM. London. Improvements in conduits for electrical conductors, and in the manufacture of the same.

20,302. T. G. LOVGROVE and J. W. PECHIN. London. Electrically operated alarms.

20,318. A. RECKENZAUN. London. Improvements in electric clocks, also applicable to electricity meters.

December 18, 1889.

20,326. G. KAPP. Manchester. Improvements in and connected with the field magnets of dynamo-electric machines.

20,387. J. D. F. ANDREWS. London. An electric switch.

20,393. C. F. JENKIN. London. Improvements in apparatus for lighting trains by electricity, and in the winding and regulation of dynamos for these and other purposes.

20,400. T. J. MURDAY. London. Improvements in apparatus for obtaining a record of the movements of indicators by means of electricity.

December 19, 1889.

20,451. K. W. HEDGES. London. Improvements in electric safety plugs, and appliances in connection therewith.

December 20, 1889.

20,486. G. E. B. PRITCHETT and H. R. LOW. Stortford. An improved system of distributing electricity by means of secondary generators in conjunction with underground conductors.

SPECIFICATIONS PUBLISHED.

1888.

17,155. LANCASTER. Electrical spring switches. (Price 8d.)

17,178. MORDEY. Electric motors. (Price 6d.)

17,795. BROCKIE. Electric arc lamps. (Price 8d.)

18,035. Sir WM. THOMSON. Electrostatic apparatus for measuring potentials. (Price 11d.)

18,035A. Sir WM. THOMSON. Ampere gauge and connections. (Price 11d.)

1889.

1,673. PHILLIPPART. Secondary batteries. (Price 8d.)

15,489. TEAGUE. Electricity meters. (Price 11d.)

15,820. SMITH. Secondary battery. (Price 8d.)

16,564. LAKE (Morgan). Winding clocks electrically. (Price 8d.)

17,221. TODD and others. Electric telephonic apparatus. (Price 8d.)

CITY NOTES, &c.

BRAZILIAN SUBMARINE TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 27th amounted to £5,027.

COMMERCIAL CABLE COMPANY.—The numbers are published of the debentures of this Company which have been drawn for payment at par on January 15, 1890, from which date interest will cease.

HALIFAX AND BERMUDAS CABLE COMPANY.—Notice is given that the coupons of the Four and a-Half per Cent. Debentures of this Company, due December 31, 1839, are payable at their bankers', Messrs. Dimsdale, Fowler, Barnard, and Dimsdales, 50, Cornhill, on and after that date. Coupons must be left three clear days.

SPIEL'S PATENT PETROLEUM ENGINE COMPANY (LIMITED).—The annual general meeting of the shareholders of this Company was held, on Monday last, at the offices of the Company, Leadenhall-buildings, E.C. Mr. Frederick Heritage (managing director) occupied the chair, and in proposing the adoption of the report and balance-sheet, stated that the profit and loss accounts on June 30, 1888, showed a debit of £288. 9s. 2d., and that amount had been increased by the sum of £736. 19s. 10d., notwithstanding that the expenses of the Company were still kept within the lowest possible limit, that the rent of the offices had been reduced, and that the Directors still received no fees. In the month of April last, Messrs. Shirlaw and Co. ceased to manufacture Spiel's engines, their right to do so being now the subject of legal proceedings. The Board were hopeful that satisfactory arrangements would shortly be concluded with another firm, who were now making an exhaustive test of the engines at their own works, and in that case there could be little doubt that the success of the Company, so long delayed, would be realised. The motion was seconded by Col. Le Champion, and carried. Mr. D. W. Forbes was re-elected as a Director, and a vote of thanks was accorded the Chairman.

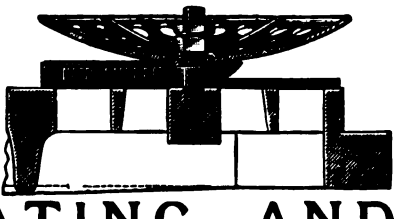
UNITED RIVER PLATE TELEPHONE COMPANY.—The Directors of this Company have declared an interim dividend for the half-year ended September 30th of 2 per cent. (being 2s. per share), tax free, payable on January 15th.

WEST COAST OF AMERICA TELEGRAPH COMPANY.—The Directors of this Company have declared a second interim dividend of 5s. per share in respect of 1889, tax free, payable January 9th.

WESTERN AND BRAZILIAN TELEGRAPH COMPANY.—The traffic receipts of this Company for the week ended December 27th, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company (Limited), were £3,683.

NEW VALVE

No Rubber, Percha, or Leather.



One-half the price of Rubber or Metal.

FOR CIRCULATING AND AIR PUMPS.

Unaffected by any Lubricating Oils. Does not Expand in diameter. Feed Water may be worked at any temperature Suitable for any shaped guards. Only one quality manufactured.

"12, John-street, Sunderland, 26th Sept. 1885.

"DEAR SIRS,—In reply to your letter of the 25th inst., the Valves I got from you have done their work well, and ARE AN UNQUALIFIED SUCCESS. I will continue to get them from you as required.—Yours faithfully, JAMES WESTOLL."

For further Testimony and Prices, apply to MOSSES & MITCHELL, 68-71, Chiswell Street, London.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 603.—Vol. XXIV. FRIDAY, JANUARY 10, 1890. Price Sixpence.

NOTES.

Dr. Hopkinson's work in the domain of magnetism is so well known to the readers of *The Electrician* that his Presidential Address to the Institution of Electrical Engineers, dealing with recent advances in the knowledge of the magnetic properties of iron and other metals, is certain to be welcome. Concerning the address itself we shall have something to say on a future occasion. It is a matter of congratulation that so large a proportion of the recent work has been accomplished by English and English-speaking investigators.

The tenth anniversary of the formation of the Brush Company was celebrated in a manner worthy of the sturdy old company which has so successfully weathered the storms of the past, and which we all hope will have its full share of the present prosperity. The dinner at the Hotel Métropole was, as Sir Frederick Bramwell wittily remarked, conceived in a fine spirit of Christian revenge; for not only were those invited whom one might expect to see present on such an occasion, but among the 150 or 160 guests who enjoyed the hospitality of the Brush Company on Monday evening were some of that Company's doughtiest opponents in the Law Courts, and several of its most formidable trade competitors. The speeches were of the conciliatory and sanguine character usual to after-dinner utterances. Lord Thurlow, in proposing the "Learned and Scientific Societies," alluded in eloquent terms to the debt which commerce owed to science. Sir John Pender, in responding for the "Electrical Industry," dwelt on the difficulties which in early days had beset submarine telegraphy, and prophesied that in the same way as these difficulties were now things of the past, so the few remaining problems which had still to be solved in connection with the electrical distribution of light and power would shortly be overcome. Finally Sir Frederick Bramwell proposed prosperity to the Brush Electrical Engineering Company in one of the most amusing of speeches. In one of the numerous speeches which he was called upon to make in the course of the evening, Lord Thurlow announced that the Brush Company might shortly be expected to declare a dividend. For our part we can only hope that when the time arrives for the Company to celebrate its coming of age, it will be able to show an unbroken succession of dividends dating from the tenth year of its existence.

The St. Pancras Vestry, as we mentioned in our last issue, have finally resolved to give effect to their Provisional Order of 1883, and will shortly advertise for tenders for a central station of 10,000 light capacity. Considering that the population of the parish is some 300,000, a station of this size is by no means too large, even as a beginning. This decision has not been come to without the usual number of reports, since, in addition to a lengthy review of the whole question by Mr. Eccleston Gibb, the Vestry have had before them within the last nine months no less than four reports from Prof. Robinson.

The chief point of interest in Prof. Robinson's final report, which we publish in another column, is the recommendation that the continuous-current transformer system should be adopted. The Metropolis already affords examples of some half a dozen different methods of distribution, and there is no reason why the continuous-current transformer system should not be included among them. It will be noticed that Prof. Robinson bases his estimates on the assumption that 80 Board of Trade units will be sold per lamp per annum. Taking the lamps as 60-watt lamps, this is equivalent to an annual output of nearly 1,400 hours at full load, a figure which is considerably higher than previous experience in this country has shown to be the case. On the other hand, 2,830 tons of coal for an output of 825,000 units, or 6lb. of coal per electrical horse-power hour, ought certainly to be an ample allowance.

In fixing the number of arc lamps for street lighting at 90 the St. Pancras Vestry were guided by the fact that they are permitted by Parliament to make seven per cent. profit, which may be applied to the relief of the rates in any way they think proper. Seven per cent. on an outlay of £50,000 is £3,500, a profit which, according to Prof. Robinson's estimates, can be made by supplying current at 4½d. per unit, and which would pay for the working of 90 arc lamps, while at the same time relieving the rates of the £1,120 at present charged for 400 gas lamps.

We had the pleasure a few days ago of witnessing an interesting demonstration of the capabilities of the Thomson electric welding process. The more one sees of this process the more apparent it is that, except for such *tours de force* as the welding of manganese steel and other refractory alloys, the whole art of electric welding is one which ought to be learned by a man of

Digitized by Google

ordinary intelligence in a comparatively short space of time. Its other great advantages of rapidity, cleanliness, and wide applicability are too well known to need emphasising. The process is now about to be pushed in this country, and we can see no reason for a success less marked than that attained in the United States.
